NCTAMS LANT Det	Naval Computer and Telecommunications Area Master Station Atlantic Detachment
ng/kg	nanogram per kilogram
NRWQC	National Recommended Water Quality Criteria
NTCRA	non-time critical removal action
PAH	polycyclic aromatic hydrocarbon
PAL	project action level
PCB	polychlorinated biphenyl
PCE	tetrachloroethene
PFAS	per- and polyfluoroalkyl substance
PFC	perfluorinated compound
PFOA	perfluorooctanoic acid
PFOS	perfluorooctanesulfonic acid (perfluorooctane sulfonate)
PID	photoionization detector
ppm	part per million

PSA	preliminary site assessment
PSL	project screening level
QC	quality control
QL	quantitation limit
RAG	Remedial Action Guideline
RAO	remedial action objective
RI	Remedial Investigation
RME	reasonable maximum exposure
RPD	relative percent difference
RSE	removal site evaluation
RSL	regional screening level
SEV	screening ecological value
SI	Site Inspection
SRA	Screening Risk Assessment
SVOC	semivolatile organic compound
SYA	Salvage Yard Area
TAL	target analyte list
TCDD	tetrachlorodibenzo-p-dioxin
TCE	trichloroethene
TCLP	toxicity characteristic leaching procedure
TEQ	toxicity equivalent
TOC	total organic carbon
TPH	total petroleum hydrocarbons
TRV	toxicity reference value
TSCA	Toxic Substances Control Act
U.S.	United States
UCL	upper confidence limit
UFP-QAPP	Uniform Federal Policy for Quality Assurance Project Plans
UNITEC	Universe Technologies, Inc.
USEPA	United States Environmental Protection Agency

VISL	Vapor Intrusion Screening Level
VLF	Very Low Frequency
VOC	volatile organic compound
VPH	volatile petroleum hydrocarbons

EXECUTIVE SUMMARY

Resolution Consultants (Resolution) has prepared this Remedial Investigation (RI) report on behalf of the Naval Facilities Engineering Command (Navy) under the Comprehensive Long-Term Environmental Action Navy contract number N62470-11-D-8013. This RI was conducted in accordance with the state agreement known as the Administrative Order by Consent of 2002 between the Navy and the Maine Department of Environmental Protection (MEDEP), the lead environmental regulatory agency for the Naval Computer and Telecommunications Area Master Station Atlantic Detachment in Cutler, Maine (Cutler). The state agreement allows the Navy to follow the Comprehensive Environmental Response, Compensation, and Liability Act requirements through the Navy Environmental Restoration Program. This RI report summarizes the activities associated with the investigation of contamination and several removal actions performed at the site. The primary objectives of this RI report are to determine the nature and extent of chemicals of concern (COCs), assess potential threats to human health and the environment, and provide a basis for determining whether or what types of response actions are required.

Site 1, Fire Training Area (FTA), occupies 10.27 acres (**Figure ES-1**). The FTA was located within an abandoned gravel pit that was historically used for fire-training exercises. According to a 1988 preliminary assessment report, fire-training activities utilized two 4,200-gallon tanks, approximately 8 feet (ft) in diameter and 8 ft high in size, which had been cut in half. Waste fuel oil was burned in these tanks. The tanks were partially filled with water before the waste fuel oil was added and ignited. Some of the fuel oil is believed to have been released to the environment due to overfilling or overflow resulting from precipitation (NEESA 1988). The Drum Disposal Area (DDA), previously known as Site 5, was combined with the FTA in early 2012 due to their close proximity and similar contaminants.

Several previous investigations and removal actions have been performed at Site 1 between 1991 and 2016 by other contractors to address environmental contamination. As part of assessing the contaminant nature and extent, analytical results were compared to project screening levels (PSLs). For the FTA, PSLs are based on United States Environmental Protection Agency (USEPA) Regional Screening Levels, USEPA Maximum Contaminant Levels, and USEPA and MEDEP surface water criteria. While MEDEP also provides Remedial Action Guidelines (RAGs), the RAGs are not applicable to the FTA because the site-specific risk assessments were used to determine the need for remedial action and develop clean-up goals. Furthermore, the selected PSLs were overall more conservative than MEDEP RAGs. Therefore, the selected human health PSLs were used to conservatively evaluate the nature and extent of contamination at the FTA. Analytical data were then evaluated in a human health risk assessment (HHRA) and an ecological risk assessment (ERA). Those compounds that pose potential unacceptable risks were categorized as chemicals of concern (COCs). Other factors are also considered in identifying or eliminating COCs and include conservativeness of the risk assessment processes or other information known about the COCs.

Soil

Total polychlorinated biphenyls (PCBs) (primarily PCB Aroclor-1260), polycyclic aromatic hydrocarbons (PAHs), and two metals (arsenic and manganese) were identified above PSLs and potentially posing a risk in soil. **Table ES-1** summarizes the maximum concentrations detected for these chemicals.

Table ES-1:
Maximum Concentrations of Selected Chemicals Identified Above PSLs in Soil

Chemical	Location (depth)	Concentration (mg/kg)
PCB Aroclor-1260	PCBAREA1-013	610
Benzo(a)pyrene	FTA-SB-216 (0 - 2 ft)	4.3
Arsenic	FTA-SB-214 (2 - 6 ft)	25.1
Manganese	FTA-SB-201 (0 - 2 ft)	8,600

PCB Aroclor-1260 had the highest frequency of detection of the PCB Aroclors. PCB Aroclor-1260 was detected in 103 of 107 surface soil samples and 64 of 114 subsurface soil samples. Benzo(a)pyrene was detected above PSLs in 10 of 37 surface soil samples and only one subsurface soil sample. Arsenic and manganese were detected in all 37 of the surface soil samples and all 54 subsurface soil samples.

From 1999 to 2013, approximately 40,326 tons of soil have been removed from the FTA during the historical removal actions at the site to remove petroleum and PCB-contaminated soil. In the nature and extent evaluation, and in calculating risks, any RI sample collected from soil that was excavated was excluded from the data set.

Groundwater

Arsenic, manganese, trichloroethene and vinyl chloride were identified above PSLs and potentially posing a risk in groundwater. **Table ES-2** summarizes the maximum concentrations detected for these chemicals.

Table ES-2:
Maximum Concentrations of Selected Chemicals Identified Above PSLs in Groundwater

Chemical	Location	Concentration (µg/L)
Arsenic	MW-5	16
Manganese	MW-9	3,850
Trichloroethene	MW-206	10
Vinyl Chloride	MW-9	0.84

Based on September 2015 water level data from 26 site monitoring wells, the depth to groundwater ranges from less than 0.5 ft to approximately 13 ft below ground surface, with shallow groundwater flowing generally to the north. Hydrographs of groundwater elevation data reveal no discernible trends in seasonal groundwater flow patterns. Hydraulic gradient values calculated for the site ranged 0.0310 foot per foot (ft/ft) in June 2015 to 0.0217 ft/ft in September 2015. From 1999 to 2013, approximately 1.8 million gallons of water were pumped and treated by dewatering systems during soil removal actions.

Groundwater samples collected from site monitoring wells indicated maximum concentrations of perfluorooctanesulfonic acid (PFOS) and perfluorooctanoic acid (PFOA) were detected above the PSLs in the northern portion of the site in MW-11 (0.25 µg/L of PFOS) and MW-14 (0.45 µg/L of PFOA).

Arsenic was detected above the PSL at a maximum concentration of 16 µg/L in MW-5. The results of speciated chromium sampling collected from MW-208 (in a well at the upgradient part of the site) indicated a concentration of 9.97 µg/L total chromium and 4.8 µg/L hexavalent chromium, above the PSL for hexavalent chromium of 0.035 µg/L. The maximum concentration of manganese was detected in the northern portion of the site in MW-9 at 3,850 µg/L.

Semivolatile organic compounds infrequently detected above PSLs include 1,1-biphenyl and hexachlorocyclopentadiene. Volatile organic compounds (VOCs) including cis-1,2-dichloroethene, trichloroethene, and vinyl chloride are relegated to a small plume of low to trace VOC levels, situated between well MW-206, located in the vicinity of the fire-training area, and downgradient wells MW-11, MW-9, MW12, and MW-10. Groundwater samples obtained from MW-206 exhibited the following VOC results in September 2015: trichloroethene (10 µg/L); vinyl chloride (0.056 µg/L); and cis-1,2-dichloroethene (22 µg/L). Well MW-206 has exhibited consistent concentrations of these three chemicals since 2012. Groundwater samples obtained from downgradient monitoring wells have shown low levels of VOCs, including a maximum vinyl chloride concentration of 0.84 µg/L at MW-9.

Surface Water

PCB Aroclor-1254, PAHs, and three metals (arsenic, manganese, and thallium) were identified above PSLs in surface water. **Table ES-3** summarizes the maximum concentrations detected for these chemicals.

Table ES-3:
Maximum Concentrations of Selected Chemicals Identified Above PSLs in Surface Water

Chemical	Location	Concentration (µg/L)
PCB Aroclor-1254	FTA-SW-06	0.38
Indeno(1,2,3-cd)pyrene	FTA-SW-06	0.16
Arsenic	FTA-SW-06 FTA-SW-07	7.9
Manganese	FTA-SW-04	1,190
Thallium	FTA-SW-02	0.32

Surface drainage at Site 1 flows towards surrounding wetland areas or to the nearby stream located approximately 1,200 ft to the northeast. Arsenic, manganese, and thallium were the only metals that exceeded the human health PSLs in surface water. PCB Aroclor-1260 was not detected in any surface water sampling locations. PCB Aroclor-1254 was detected at one surface water sampling location (FTA-SW-06) in 2014. Several PAHs were also detected at FTA-SW-06 above the human health PSLs. The highest concentration of PAHs identified at location FTA-SW-06 is indeno(1,2,3-cd)pyrene at a concentration of 0.16 µg/L. The PAH exceedances of PSLs are limited to one location; therefore, PAHs in surface water are not a widespread problem.

Sediment

Total PCBs (primarily PCB Aroclor-1260), PAHs, and two metals (arsenic and chromium) were identified above PSLs in sediment. **Table ES-4** summarizes the maximum concentrations detected for these chemicals.

Table ES-4:
Maximum Concentrations of Selected Chemicals Identified Above PSLs in Sediment

Chemical	Location	Concentration (mg/kg)
PCB Aroclor-1260	FTA-SED-04	2.1
Benzo(a)pyrene	FTA-SED-01	2.4
Arsenic	FTA-SED-04	19
Chromium	FTA-SED-07	33.7

PCB Aroclor-1260 was detected in 15 of 16 sediment sampling locations. Benzo(a)pyrene was detected in 8 of 16 sediment sampling locations above the PSL. Arsenic concentrations were detected in all sediment samples and exceeded the sediment PSL in 15 of 16 sampling locations. Total chromium exceeded the sediment PSL in all 16 samples. Hexavalent chromium was not

detected in sediment. During this evaluation and in the risk assessment, it was assumed that the chromium in sediment was entirely trivalent chromium and the trivalent chromium PSL was used.

Human Health Risk Assessment Summary

The HHRA included a quantitative evaluation of potential human exposures to surface soil, subsurface soil, groundwater, and wetland surface water and sediment. Exposure scenarios were: Current/Future Construction Worker; Current/Future On-Site Recreational User/Trespasser; Future Outdoor Industrial Worker; Future Indoor Industrial Worker; and Hypothetical Future On-Site Resident.

For soil, two soil exposure areas (**Figure ES-2**) were defined and referred to as Soil Exposure Area 1 and Soil Exposure Area 2 within the FTA site boundaries. Soil Exposure Area 1, (5.56 acres) includes all soil within the FTA boundaries outside of Soil Exposure Area 2. Soil Exposure Area 2 (1.45 acres), is located in the southern portion of the FTA. In general, Soil Exposure Area 1 contains lower chemical of potential concern (COPC) concentrations and Soil Exposure Area 2 contains higher COPC concentrations. The soil exposure areas do not include the wetlands, which were treated as a one separate exposure area for surface water and sediment. Groundwater exposure was evaluated based on groundwater data collected from permanent monitoring wells between 2012 and 2016. Upgradient wells not affected by site activities were excluded in the evaluation of receptor risks.

The HHRA concluded that chemicals potentially posing a risk for one or more receptors included:

- Surface Soil
  - *Soil Exposure Area 1:* Manganese
  - *Soil Exposure Area 2:* Manganese, benzo(a)pyrene, and Total PCBs (primarily PCB Aroclor-1260)
- Subsurface Soil
  - *Soil Exposure Area 1:* Manganese
  - *Soil Exposure Area 2:* Arsenic, manganese, and Total PCBs (primarily PCB Aroclor-1260)
- Groundwater (hypothetical future drinking water scenario)
  - Arsenic
  - Manganese
  - Trichloroethene
  - Vinyl chloride

Ecological Risk Assessment Summary

The ERA evaluated the potential for risks to ecological receptors exposed to COPCs in surface soil, surface water, and sediment. The first ERA step was screening of chemicals against very conservative generic ecological standards. Based on this Tier 1 ecological Screening Risk Assessment, a Tier 2, Step 3a baseline ERA (BERA) was performed using more realistic assumptions more closely reflecting site conditions.

The Tier 2, Step 3a BERA concluded that there may be a potential for risks to small insectivorous birds and mammals (American robin and the short-tailed shrew) exposed to Total PCBs in surface soil. It was also concluded that no further evaluation is warranted for the following receptors:

- Terrestrial Plant Community
- Soil Invertebrate Community
- Freshwater Benthic Invertebrate Community
- Freshwater Aquatic Community
- Wildlife In Freshwater Exposure Areas
- Herbivorous Wildlife in Terrestrial Exposure Areas

Conclusions and Recommendations

The HHRA concluded that human health risks may exist for the following receptors: Current/Future Construction Worker; Current/Future On-Site Recreational User/Trespasser; Future Outdoor Industrial Worker; and Hypothetical Future On-Site Resident. Risk drivers in soil were Total PCBs, benzo(a)pyrene, arsenic, and manganese. Risk drivers in groundwater include trichloroethene, vinyl chloride, arsenic, and manganese. No risk drivers were identified in surface water or sediment in the wetland area.

The ERA concluded that there may be a potential for risks to small insectivorous birds and mammals (American robin and the short-tailed shrew) due to exposure to Total PCBs in surface soil and due to consumption of earthworms with bioaccumulated PCBs from terrestrial portions of the former FTA.

Arsenic was found to have concentrations in site media less than or consistent with concentrations in site background . The highest manganese subsurface soil detection (1,530 mg/kg at FTA-SB-214) is located in the southwestern portion of the site. There are no reported uses of metals at the FTA in a manufacturing process or primary waste storage or disposal. From 1999 to 2013, approximately 1.8 million gallons of water were pumped and treated and approximately 40,326 tons of soil have been removed from the FTA during the historical removal actions at the site. Based on the data that show the remaining site soil metals concentrations are within or similar to

site background levels, no release of metals to site media is indicated and remediation of metals is not warranted.

PAHs are anthropogenic compounds that are found in man-made sources and are persistent in the environment. PAHs also occur naturally. PAHs are present in oil, coal, and tar deposits and in asphalt pavement as well as natural deposits of peat. Their presence at the FTA in soils is consistent with their slow environmental degradation and the presence of peat deposits at the site. Based on this information, a release of PAHs to site media appears unlikely.

Based on the investigations performed and the findings of the risk assessments, the conceptual site model presented in **Section 7.0** was updated to illustrate the distribution of COCs in site media that warrant being addressed in a Feasibility Study (FS). The following chemicals and areas will be evaluated in a FS:

- PCBs in surface soil and subsurface soil are present in the vicinity of the former fire-training activities and the DDA. A remaining PCB-impacted area that was left behind after the 2013 AGVIQ excavation represents an area of unacceptable risk. The total extent of the area affected by PCBs to be addressed in the FS is approximately 300 square ft, located in the southwest portion of the site. The FS will focus on remedial alternatives to address the unacceptable risk from PCBs in soil in this portion of the site.
- Benzo(a)pyrene is present in surface soil in Soil Exposure Area 2 at concentrations that represent potentially unacceptable risks to hypothetical residential and recreational receptors. There are no potentially unacceptable risks for industrial receptors. Therefore, while benzo(a)pyrene will be addressed in the FS, cleanup actions are unlikely as residential and recreational future site uses are not anticipated.
- A small plume of chlorinated solvents is present at the site. However, migration appears limited because trichloroethene and its breakdown product cis-1,2-dichloroethene are not present in monitoring wells downgradient of the potential source area. This empirically suggests that trichloroethene may be degrading as it migrates. Only trace amounts of the next degradation daughter product, vinyl chloride, are found in the downgradient portions of the site. This is supported by the negative oxidation reduction potential values measured in the field during the September 2015 groundwater sampling event. The FS will focus on remedial alternatives to continue monitoring the VOCs in groundwater.

1.0 INTRODUCTION

Section 1.0 discusses the purpose of this Remedial Investigation (RI) report, site background, and report organization.

1.1 Purpose of Report

Resolution Consultants has prepared this RI report on behalf of the Naval Facilities Engineering Command (Navy) under the Comprehensive Long-Term Environmental Action Navy contract number N62470-11-D-8013. This RI report was conducted in accordance with the Administrative Order by Consent between the Navy and the Maine Department of Environmental Protection (MEDEP), which is the lead regulatory agency for the Cutler Environmental Restoration Program. The state agreement allows the Navy to follow the Comprehensive Environmental Response, Compensation, and Liability Act requirements through the Navy Environmental Restoration Program. This RI report provides a summary of investigation activities conducted at Site 1, Fire Training Area (FTA) and the Drum Disposal Area (DDA), located at the Naval Computer and Telecommunications Area Master Station Atlantic Detachment (NCTAMS LANT Det) in Cutler, Maine (Cutler) (**Figure 1-1**). Site 1 (FTA) is defined as a former gravel pit that was used by the Navy for firefighting training exercises from the early 1960s to the 1980s. The DDA is defined as a disposal area located on the southern edge of the FTA. Since the DDA was physically located within the boundaries of the FTA, the FTA and DDA were combined in 2012 and all environmental issues are being addressed as Site 1. For this RI report, the discussion of Site 1 includes all investigation activities that have occurred at both the FTA and the DDA.

The primary objectives of this RI report are to determine the nature and extent of chemicals of concern (COCs), assess potential threats to human health and the environment, and provide a basis for determining whether or what types of response actions are required. This report includes data collected from multiple investigations conducted at the FTA and DDA between 1991 and 2016. Specific data sets are summarized in **Section 2.4**. The information, data, and interpretations presented in this RI report serve as the basis for the screening level human health risk assessment (HHRA), included as **Section 6.0** of this RI report. The objective of the screening level HHRA is to evaluate whether residual soil concentrations of Site 1-related constituents have impacted the environment at concentrations that may pose unacceptable risk to human health. The objective of the ecological risk assessment (ERA), included as **Section 7.0** of this RI report, is to evaluate whether Site 1-related constituents pose unacceptable risk to the environment.

1.2 Site Background

Section 1.2 discusses the site description, history, and previous investigations.

1.2.1 Site Description

The NCTAMS LANT Det Cutler facility is located near the town of Cutler, Washington County, Maine. Construction began in the late 1950s, and on June 23, 1961, NCTAMS LANT Det Cutler was established as a communications facility that provides radio signal transmissions with United States (U.S.) ships, planes, and submarines operating mainly in the North Atlantic and Arctic Oceans, and the Mediterranean Sea. The entire facility occupies approximately 3,000 acres originally consisting of three main areas: (1) the Administrative and Housing Area, (2) the High Frequency (HF) Area, and (3) the Very Low Frequency (VLF) Peninsula Area. In 2000, the Navy transferred military operations of these areas to civilian staffing (**Figure 1-1**). With that, approximately 80 acres of the facility, including the living quarters and support facilities for Navy personnel (the Administrative and Housing Area), were transferred to the Cutler Development Corporation. The Navy maintains ownership of the HF and VLF Peninsula Areas, which continue to operate with civilian staffing.

The FTA is approximately 10.27 acres in size and located in the northern portion of the Cutler Peninsula, to the north of the VLF Peninsula, east of Holmes and Machias Bays, and west of Little Machias Bay (**Figure 1-1**). Undeveloped forested land and several freshwater wetlands surround the site. The site was historically used for firefighting operations and disposal of fuel oil. A 2009 removal action of impacted soil was conducted in the center of the site and an existing wetland was enhanced during restoration activities. The rest of the site mainly consists of open or forested area, with forested area around the perimeter. The DDA is located in the southwest corner of the FTA, immediately to the south and directly upgradient of the 2009 enhanced wetland (**Figure 1-2**). During previous removal actions, 76 waste oil drums and drum remnants were removed from the DDA.

1.2.2 Site History

The FTA is an abandoned gravel pit that was historically used for fire-training exercises by NCTAMS LANT Det Cutler personnel from the 1960s to the 1980s. According to a preliminary assessment report completed by the Naval Energy and Environmental Support Activity in 1988, fire-training activities utilized two 4,200-gallon tanks, approximately 8 feet (ft) in diameter and 8 ft high in size, that had been cut in half. Waste fuel oil was burned in these tanks. The tanks were partially filled with water before the waste fuel oil was added and ignited. Some of the fuel oil is believed to have been released to the environment due to overfilling or overflow resulting from precipitation (NEESA 1988). According to Naval Computer and Telecommunications Area Master Station (NCTAMS) Fire Department officials, a maximum of 300–400 gallons of waste fuel were burned each year (HMM 1994). Additionally, it was reported that waste No. 6 fuel oil was brought

to the FTA and spread on the ground in the early 1980s when base Power Plant engines were switched from No. 6 fuel oil to No. 2 fuel oil.

The DDA was originally identified as Area of Concern (AOC) 31 (FTA DDA) in the 2007 Preliminary Site Assessment (PSA) Report based on the discovery of a drum in 2006. In 2010, the DDA was elevated from an AOC to an Installation Restoration (IR) Site. The DDA was combined with the FTA in early 2012 due to their close proximity and similar contaminants, and both sites are referred to together as Site 1 (FTA).

1.2.3 Previous Investigations

Several previous investigations and removal actions have been performed at Site 1 between 1991 and 2016 by other contractors to address environmental contamination. **Table 1-1** presents a brief summary of those previous investigations and the corresponding reports. More details of the previous investigations key figures from those reports are included in **Appendix A**.

Until 2012, the FTA and the DDA were investigated separately. To differentiate the locations of the activities, **Table 1-1** specifies where the investigation occurred (FTA or DDA) until 2012 when the two sites were combined as Site 1 FTA.

1.3 Report Organization

The subsequent sections of this RI report provide the following information:

- **Section 2.0** provides discussions of investigation activities conducted at the FTA and the target constituents and data sets in support of this RI report.
- **Section 3.0** provides the physical characteristics of Site 1.
- **Section 4.0** provides the nature and extent of the contaminants.
- **Section 5.0** provides the fate and transport of the contaminants.
- **Section 6.0** includes the HHRA and the ERA. The complete HHRA is included as **Appendix D** and the complete ERA is included as **Appendix E**.
- **Section 7.0** provides the Conceptual Site Model (CSM).
- **Section 8.0** provides the summary, conclusions, and recommendations based on the investigatory findings.
- **Section 9.0** is a list of references used in this RI report.

A summary of previous investigations and historical figures referenced in the RI report is included in **Appendix A**. Data summary tables of the historic and 2015 and 2016 data referenced in the RI report are included in **Appendix B**. A background reference data evaluation is included in

Appendix C. The HHRA is included in **Appendix D** and the ERA in **Appendix E**. **Appendix F** includes the August 2017 Technical Memorandum Evaluation of Groundwater Analytical Results for the FTA for sampling conducted in September 2015. A White Paper that addresses hexavalent chromium in soil and sediment at the FTA is included in **Appendix G**.

2.0 STUDY AREA INVESTIGATION

This report uses data from historical investigation and removal activities obtained prior to the RI and during several RI-specific phases of sampling from 1991 to 2016 (**Section 1.2**). Figures in **Appendix A** of this report present the historical sample locations in and around Site 1. Many previous sample locations have been removed as part of the interim removal actions, as discussed in **Section 1.2.3** and **Appendix A**. Samples that were excavated have been omitted from the data set used in this evaluation.

Samples that were not removed as part of the historical interim removal actions are used in this evaluation as they are still present in media in and around Site 1. The data are included in **Appendix B**.

Site monitoring wells were sampled most recently as part of this RI in 2015 to obtain current data to evaluate the plume stability and support the risk assessment. The nature and extent of groundwater contamination including contaminant trends from 2002 to 2015 are summarized in **Section 4.0**. The 2017 Technical Memorandum Evaluation of Groundwater Analytical Results is included in **Appendix F**.

2.1 Site Characterization Field Activities

Historical site characterization of Site 1 of surface features, contaminant sources, meteorology, human population, ecology, site geology, and characterizations of site media not conducted by Resolution are summarized in **Section 1.0** and **Appendix A**. Characterization activities conducted by Resolution are described in the following sections.

2.1.1 Groundwater Investigations

Groundwater samples were collected during 2014 at 12 existing wells (MW-1, MW-5, MW-9, MW-10, MW-11, MW-12, MW-14, MW-206, MW-208, MW-210, MW-218, and DP-35). The samples were analyzed for volatile organic compounds (VOCs), volatile petroleum hydrocarbons (VPH)/extractable petroleum hydrocarbons (EPH), semivolatile organic compounds (SVOCs), and metals (total and dissolved) to confirm previous groundwater conditions. Additionally, groundwater samples were collected in 2012, 2014, and 2015 and analyzed for per- and polyfluoroalkyl substance (PFAS) because these emerging contaminants are found in aqueous firefighting foams used at FTAs. Monitoring well MW-210 was also analyzed for polychlorinated biphenyls (PCBs) because it is near the former DDA. One groundwater sample collected from monitoring well MW-208 in November 2016 was analyzed for both total and hexavalent chromium. Water level measurements were conducted in June and September 2015 to develop groundwater contours and interpret flow direction.

Groundwater samples were collected in accordance with the U.S. Environmental Protection Agency (USEPA) Low Stress (Low Flow) Purging and Sampling Procedure (USEPA SOP-GW001, Revision 2010). A peristaltic pump was used for groundwater sampling. Dedicated tubing was used at each monitoring well to avoid potential cross-contamination between monitoring wells. Samples collected for dissolved metals analysis were filtered in the field using a new, disposable in-line 0.45-micron (pore size) filter and a pump.

Field water quality parameters were monitored using an YSI 600 series (or similar) meter coupled with a flow-through cell. Turbidity was measured separately using a LaMotte Model 2020 or equivalent nephelometer. Field water quality parameters are detailed in the 2017 Technical Memorandum Evaluation of Groundwater Analytical Results provided in **Appendix F**.

Groundwater samples were containerized for laboratory analyses as indicated in Worksheet #18 of the project Sampling and Analysis Plan (Resolution 2015), which includes analytical methods, sample containers, preservation, and holding time requirements for each analytical group.

2.2 Sampling for Hexavalent Chromium

Soil, sediment, and groundwater samples were collected during previous investigations at the FTA and analyzed for metals, including total chromium. Since the speciation of the chromium was unknown, the chromium results were conservatively evaluated as hexavalent chromium in soil and sediment, as requested by MEDEP (Tetra Tech 2014). The evaluation of total chromium as 100-percent hexavalent chromium requested by MEDEP is a conservative approach and leads to overestimation of the potential risk or hazard index (HI) for total chromium.

During November 2016, samples were collected and analyzed for total chromium and hexavalent chromium in order to determine whether chromium present in site media is in the more toxic hexavalent form. Trivalent chromium concentrations were calculated by subtracting hexavalent chromium from the total chromium result. At the FTA, 10 soil samples and one sediment sample were collected. One sample of groundwater was also collected and analyzed from well MW-208 for total chromium, hexavalent chromium, and trivalent chromium in November 2016. Total chromium has never been detected in surface water at the FTA and therefore was not included in the November 2016 sampling.

Sampling was conducted in accordance with the Field Sampling Plan (Resolution 2016) at selected locations based on historical high total chromium concentrations. The Field Sampling Plan was reviewed by the Navy and MEDEP. MEDEP responded that due to soil disturbance in the area, the originally proposed locations may be compromised and not representative of undisturbed soil. The samples collected as part of this field effort reflect the revised sample locations in areas known to be undisturbed, as approved by Navy and MEDEP.

Appendix B, Tables B-8, B-9, and B-10 present the validated results of the November 2016 sampling. A White Paper that addresses hexavalent chromium in soil and sediment at the FTA is included in **Appendix G**.

2.3 Target Constituents

Past activities at the FTA have included historical use for fire-training exercises from the 1960s to the 1980s during which PFAS were likely used in firefighting foams; spreading of waste No. 6 fuel oil on the ground at the FTA in the early 1980s when base Power Plant engines were switched from No. 6 fuel oil to No. 2 fuel oil; and disposal and burial of drums of waste oils and fluids.

PFAS include perfluorooctanesulfonic acid (also known as perfluorooctane sulfonate [PFOS]) and perfluorooctanoic acid (PFOA). According to the USEPA website (2017), USEPA uses PFAS rather than perfluorinated compounds (PFCs) consistently to collectively describe PFOA, PFOS, and the other chemicals in this group. This report will refer to PFOS and PFOA collectively as PFASs.

Based on the past activities, samples collected at the FTA have been analyzed for a variety of constituents. Soil samples have been analyzed for VOCs, SVOCs, PCBs, pesticides, and diesel range organics (DRO)/gasoline range organics (GRO) and metals. Groundwater samples have been analyzed for VOCs, SVOCs, PCBs, PFASs, VPH, EPH, and metals. Surface water and sediment samples have been analyzed for VOCs, SVOCs, VPH, EPH, and metals. In addition, sediment samples have been analyzed for PCBs and pesticides.

2.4 Remedial Investigation Data Set

As discussed in **Section 1.2.3**, several historical investigations and removal actions have been performed to address contamination at the FTA. Groundwater, surface soil, subsurface soil, sediment, and surface water samples have been collected at the FTA at various times between 1991 and 2016. Resolution reviewed all available data and determined the appropriate and representative data to include in this RI. The analytical data summary tables for these historical investigations are included in **Appendix B**.

The soil data set was reviewed and soil sample locations which were identified as excavated in previous removal actions were removed from the data set. Sediment samples and surface water samples collected from 2012 to 2016 and groundwater samples collected from 1999 to 2016 were also compiled in the RI data set included in **Appendix B**.

The *Background Study for Remedial Investigations for Installation Restoration Sites at NCTAMS LANT Det in Cutler, Maine* (Battelle 2005) described the collection of background surface soil samples (0 to 1 foot [ft] below ground surface [bgs]). Samples collected from 15 locations in each of the two primary soil types (glacial till and glaciomarine sediments) were considered to be

applicable to the FTA. **Appendix C** presents the background evaluation of these samples considered in the HHRA and ERA for the FTA RI.

While chemicals within background levels are not attributed to Navy activities, background levels are considered in the HHRA and the ERA included in **Appendix D** and **Appendix E**, respectively.

The analytical data set was compared against project screening levels (PSLs) to evaluate the nature and extent of contamination. The selection of PSLs is described in **Section 4.1**.

MEDEP provides Remedial Action Guidelines (RAGs) for soil, groundwater, and indoor air (MEDEP 2016) for the protection of human health. RAGs are not available for surface water or sediment, or for ecological impacts. The RAGs may be used to simplify derivation of clean-up goals in the absence of a site-specific risk assessment (MEDEP 2016). Alternatively, a site-specific risk assessment may be used to determine whether site action is warranted and, if necessary, develop site-specific clean-up goals (MEDEP 2016). The latter approach was selected for the FTA; therefore, the RAGs are not applicable to the FTA RI.

Table 2-1 and **Table 2-2** compare the PSLs with the various soil and groundwater MEDEP RAGs. For soil, the selected PSLs are lower than MEDEP RAGs for 79 of the 97 detected compounds. For groundwater, the selected PSLs are lower than MEDEP RAGs for 41 of the 44 detected compounds. Therefore, the human health PSLs were used to evaluate the nature and extent of contamination at the FTA.

2.5 Analytical Data Validation and Usability Assessment

2.5.1 Data Validation

The analyses were validated using the following documents and variances, as applicable to each method:

- September 2016 Final Sampling and Analysis Plan: Site-Specific Quality Assurance Project Plan
- U.S. Department of Defense Quality Systems Manual for Environmental Laboratories, Version 5.0, July 2013
- USEPA National Functional Guidelines for Superfund Organic Methods Data Review, August 2014

Issues identified during the data validation resulted in the application of letter qualifiers to the data to ensure reported concentrations were accurately represented. Inclusion or exclusion of data for further analysis was based on review of analytical qualifiers and performed in accordance with guidelines noted previously:

- Analytical results bearing the U qualifier (indicating that the analyte was not detected at the given reporting limit) were retained in the data set and considered non-detects. If the limit of detection (LOD) was elevated above the limit of quantitation (LOQ), the LOQ was also elevated.
- Analytical results bearing the J qualifier (indicating that the reported value was estimated because of minor anomalies with the method quality objectives) were retained at the measured concentration.
- Analytical results bearing the UJ qualifier (indicating that the analyte was analyzed, but not detected, and the associated LOD is an estimate and may be inaccurate or imprecise) were retained at the measured concentration.

The data validation report (**Appendix B**) presents explanations for all of the qualified data in greater detail.

2.5.2 Data Usability Assessment

Although the RI data are considered reliable, some degree of uncertainty is unavoidable. Specific factors that may contribute to the uncertainty of the data evaluation are described in the following sections. The following Data Quality Indicators (Precision, Accuracy, Representativeness, Comparability, Completeness, Compliance, and Sensitivity) are important components in assessing data usability. When evaluated using these parameters, the data are determined to be of high quality.

2.5.2.1 Precision

Precision is the degree of agreement among repeated measurements of the same characteristic on the same sample or on separate samples collected as closely as possible in time and place. Field sampling precision is measured with the field duplicate relative percent differences (RPDs); laboratory precision is measured with calibration verification, laboratory control spike (LCS) and matrix spike duplicate RPDs, and serial dilution percent differences.

Calibration verifications are performed routinely to ensure that instrument responses for all calibrated analytes are within established control criteria. LCS pairs are prepared by addition of known concentrations of each analyte in a matrix-free media known to be free of target analytes. LCS pairs were analyzed for each analytical batch to demonstrate the ability of the laboratory to

detect similar concentrations of a known quantity in matrix-free media. All LCS pairs met the RPD precision outlined in the Uniform Federal Policy for Quality Assurance Project Plans (UFP-QAPP).

Field duplicate pair sets were collected to assess the overall sampling and measurement error for this sampling effort. The field duplicate sample was analyzed for the same analytes as the primary field sample. An RPD of 35 percent was used to evaluate the field duplicate precision in accordance with the UFP-QAPP. The field duplicate pairs performed on field samples FTA-MW-206-091815 and FTA-MW-14-092115. Field sample FTA-MW-206-091815 displayed anomalies for barium that resulted in field sample results being flagged J. Field sample FTA-MW-14-092115 displayed anomalies for copper and nickel. The J flag means that the associated numerical results are considered approximations of the actual sample concentrations.

A serial dilution is prepared by the laboratory after digestion for the metals analyses for each preparation batch by creating a 1:5 dilution of a digestate in water. The serial dilution result should be within 10 percent of the neat digestate concentration.

2.5.2.2 Accuracy

Accuracy is confidence in a measurement. The smaller the difference between the measurement of a parameter and its true or expected value, the more accurate the measurement. The more precise or reproducible the result, the more reliable or accurate the result. Accuracy is measured through percent recoveries in the LCSs, the matrix spike pairs, and surrogates.

LCSs are prepared by addition of known concentrations of each analyte in a matrix-free media known to be free of target analytes. LCSs were analyzed for each analytical batch to demonstrate that the analytical system was in control during sample preparation and analysis. One LCS pair displayed percent recoveries greater than the upper control limit of 120 percent for tetrachloroethene (FTA-MW-11-092115 and FTA-MW-14-092115-D). Three LCS pairs displayed recoveries lower than the lower control limit, which are 2-methylphenol (30 percent) and 1,1-biphenyl (32.5 percent) for FTA-DP-35-092115, FTA-MW-10-092115, FTA-MW-1-091815, FTA-MW-12-092115, FTA-MW-14-092115, FTA-MW-14-092115-D, FTA-MW-206-091815, FTA-MW-206-091815-D, and FTA-MW-218-091815. The associated field sample results were flagged J.

A matrix spike pair is prepared, analyzed, and reported for all preparation batches. Matrix spikes demonstrate that the analytical system was in control for the matrix being tested. Matrix spike pairs were analyzed for each analytical batch to demonstrate the ability of the laboratory to recover a concentration of a known quantity in site matrix media. The matrix spike performed on field sample FTA-MW-210-092115 displayed percent recoveries less than the lower control limit for isopropylbenzene, 2-methylphenol, caprolactam, 1,1'-biphenyl, 2-chlorophenol, 3,3'-dichlorobenzidine, bis(2-ethylhexyl)phthalate, m&p cresols, dibenzo(a,h)anthracene,

indeno(1,2,3-cd)pyrene, and n-nitrosodi-n-propylamine. The associated field sample results (FTA-MW-210-092115) were flagged J.

Surrogate compounds were added to all field samples and quality control (QC) samples during sample preparation. Surrogate compounds are substances with properties that mimic the analytes of interest. Surrogate compounds are unlikely to be found in field samples, and are added to demonstrate the laboratory's ability to detect a similar compound at a known concentration. Samples FTA-MW-5-091815, FTA-MW-1-091815, and FTA-MW-14-092115-D had high recoveries of the surrogate dibromofluoromethane (SW8260 SIM), which exceeded the acceptance limit of 130 percent. FTA-MW-14-092115, FTA-MW-10-092115, FTA-MW-208-092115, FTA-MW-12-092115, and FTA-DP-35-092115 had high recoveries of the surrogates 1,2-dichloroethane-d4 and dibromofluoromethane (SW8260) which exceeded the acceptance limit of 130 percent. Since a high recovery indicated a high bias and there were no target analytes detected above the method detection limit (MDL), no qualification was necessary.

2.5.2.3 Representativeness

Representativeness qualitatively expresses the degree to which data accurately reflect site conditions. Factors that affect the representativeness of analytical data include appropriate sample population definitions, proper sample collection and preservation techniques, analytical holding times, use of standard analytical methods, and determination of matrix or analyte interferences.

Field QC samples were collected to assess the representativeness of the data collected. Field duplicates were collected at a rate of 10 percent for all discrete samples. All preservation techniques were followed by the field staff and all technical and analytical holding times were met by the laboratory. The laboratory used approved standard methods as outlined in the UFP-QAPP for all analyses.

2.5.2.4 Comparability

Comparability is the extent to which data from one study can be compared directly to either past data from the current project or data from another study. Using standardized sampling and analytical methods, units of reporting, and site selection procedures helps ensure comparability. Standard field sampling and typical laboratory protocols were used.

2.5.2.5 Compliance

Method compliance was determined by evaluating sample integrity, preservation, holding time, laboratory blanks, and calibration against method specified requirements, while applying USEPA data validation guidelines. No data require qualification based on method compliance measurements and overall method compliance is acceptable based on the data reported.

2.5.2.6 Completeness

Completeness is the overall ratio of the number of samples planned versus the number of samples with valid analyses. Completeness goals are set at 90–100 percent. Determination of completeness included a review of chain of custody records, laboratory analytical methods and detection limits (DLs), laboratory case narratives, and project requirements. Completeness also included 100-percent review of the laboratory sample data results and electronic data deliverables.

RI field activities spanned many years and occurred in several different phases. The total quantity of data collected is complete, of sufficient quality, and usable to complete the RI of the FTA and make decisions for potential cleanup.

2.5.2.7 Sensitivity

Sensitivity is the capability of a test method or instrument to discriminate between measurement responses representing different levels (e.g., concentrations) of a variable of interest. Examples of QC measures for determining sensitivity include laboratory fortified blanks, a MDL study, and calibration standards at the quantitation limit (QL). To meet the needs of the data users, project data must meet the measurement performance criteria for sensitivity and project QLs specified in the UFP-QAPP. The laboratory provided the requested MDL studies and provided applicable calibration standards at the QL. To achieve the data quality objectives for sensitivity outlined in the UFP-QAPP, the laboratory reported all field sample results at the lowest possible dilution. No non-detect field sample results were retained in the data set; all dilutions were performed appropriately and correctly.

3.0 PHYSICAL CHARACTERISTICS OF THE STUDY AREA

Section 3.0 discusses the physical characteristics of Site 1, FTA.

3.1 Surface Features

The former FTA is located at an elevation of approximately 80 ft above mean sea level (msl) based on the U.S. Geological Survey topographic map of the Machias Bay Quadrangle (USGS 2011). The ground surface slopes downward from south to north across the site and the topographic relief steepens rapidly in the southern portion of the DDA.

3.2 Surface/Water Hydrology

During the 2009 soil removal action at the FTA, a wetland area in the central portion of the site was enhanced to augment the wetland restoration area to the north (known as the Sand Wedge Excavation Area) as well as to provide additional habitat for wildlife. Surface overflow ran toward a wetland/open water habitat located in the northern portion of the site prior to the removal action. The elevation in the central portion of the FTA was reduced during the creation of the freshwater wetland, producing shallow groundwater levels at or near the ground surface. Currently, the majority of runoff drains into the wetland.

Surface drainage at Site 1 is flows towards surrounding wetland areas or to nearby streams located to the north and east.

3.3 Geology

Several removal actions have removed shallow layers of soils and replaced it with fill material consisting of cobbles, gravel, sand, and silt to at least a depth of 8 ft bgs, as reported during the October 1999 PCB soil characterization at Site 1 (EA 2000). The soil removal action areas are illustrated on Figure A-4 in **Appendix A** and described in more detail in the site history presented in **Section 1.2**.

Prior to soil removal activities, soil borings revealed a surficial geology composed of deposits from both glacial processes and marine depositional environments. According to EA Engineering, Science, and Technology, Inc. (2004), prior to soil removal activities, soils beneath the majority of the site consisted of an upper sand and gravel unit that was underlain by the silty-clay Presumpscot Formation. In the southeast portion of the site, the silty-clay is replaced by a lower sand and gravel unit. In the west/northwest portion of the site, the upper sand and gravel unit is replaced by a silt layer. The thickness of the upper sand and gravel unit ranged from 3 to 24 ft; and the thickness of the lower silty-clay unit ranged from 2 to 31 ft (EA 2004). The thickness of the lower sand and gravel unit is variable, but is at least 12.5 ft thick based on site borings. Peat deposits were noted in soil borings advanced in the immediate vicinity of the wetland near the northern portion of the site.

A depression in the lower silty-clay unit is located near the center of the FTA soil removal area (EA 2004). In this area, the silty-clay layer is found approximately 10 to 15 ft deeper than at other areas of the site. A few borings have been completed in this depression, including; FT-2, MW-6, SSS-4, DP-8, DP-41, DP-42, DP-43, SS-7, SS-10, SS-51, PECS-07, PECS-08, and PECS-09. Borings DP-41, DP-42, and DP-43 were completed as monitoring wells that are screened directly above the silty-clay layer. DP-41, DP-42, and DP-43 were destroyed during the soil excavation activities conducted between 2006 and 2009. Monitoring wells MW-16, MW-17, and MW-18 are screened in the silty-clay layer around this depression. Borings have been completed deep enough to encounter bedrock at locations MW-16 and MW-17. See **Figures 3-1** and **3-2** for geologic cross-sections of the FTA. At these locations, bedrock was inferred based on drill refusal and geologic knowledge, but was not confirmed by rock coring. Bedrock is approximately 40 ft bgs (EA 2004). Published documents have described the bedrock in the area as tuff-breccias and tuffs (EA 2004).

3.4 Hydrogeology

The former FTA is located on a State of Maine Significant Sand and Gravel Aquifer where surficial deposits are expected to yield more than 10 gallons per minute (Maine Geological Survey 2000). Based on historical water level data, the depth to groundwater ranges from less than 0.5 ft to approximately 5 to 6 ft bgs (EA 2004). There are seven water production wells at NCTAMS LANT Det Cutler, of which five are used as a water source for the facility. Two of the wells located at the Power Plant are no longer in use, due to saltwater intrusion. Three of the wells are located on the VLF Peninsula at Buildings 100, 132-135, and the Power Plant. Two of the wells are located in the area north of the VLF Peninsula at the HF Transmitter Building 400 and the Administrative and Housing Area. The only well used as a drinking water source services Building 132-135 and is regulated by the Maine Department of Health and Human Services (Tetra Tech 2007).

The 2009 soil removal action reduced the elevation in the center portion of the FTA, enhancing a freshwater wetland with groundwater likely near the surface. At the time of this removal action, dewatering was performed to allow backfilling and restoration activities. The dewatering system had a total operating capacity of 500 gallons per minute (gpm), but was normally operated at approximately 250 gpm. A total of 1.8 million gallons of water was treated by the system.

Historically, the depth to groundwater was shown to decrease from south to north across the site with a decrease in ground elevation. Based on September 2015 monitoring well gauging data, the direction of shallow groundwater flow, in the surficial materials, is generally to the north toward the wetland area. The hydrograph of groundwater elevation data from 2012 to 2015 (**Figure 3-4**) reveal no discernible trends in seasonal groundwater flow patterns.

Post-excavation groundwater elevations have not been gauged within the wetland areas; therefore, it is unknown if the groundwater potentiometric elevations have changed due to construction and

enhancements of wetlands. However, potentiometric elevations were gauged in wells located outside the wetland areas in 2015, during the monitoring well inspection survey, and potentiometric elevations ranged from approximately 91 ft in the southern portion of the site (MW-208) to approximately 67 ft in the northern portion of the site (MW-14 and MW-11). The September 2015 groundwater elevations illustrated on **Figure 3-3** are referenced to an arbitrary site datum rather than msl.

Hydraulic gradient values were calculated based on the groundwater elevation data from 2012 to 2015. Using the well pair from MW-208 to MW-11, the following hydraulic gradients were calculated: 0.0269 foot per foot (ft/ft) in November 2012; 0.0271 ft/ft in June 2014; 0.0310 ft/ft in June 2015; 0.0217 ft/ft in September 2015. No field permeability tests or hydraulic conductivity data appear to have been collected during the previous site investigations at this site.

Artesian conditions, which implies an upward hydraulic gradient from the lower silty-clay unit to the upper sand and gravel unit, have been observed in the deepest monitoring wells: MW-16, MW-17, and MW-18 (EA 2004). Monitoring wells MW-16, MW-17, and MW-18 are the only wells screened in the silty-clay unit.

3.5 Demography and Land Use

The NCTAMS LANT Det Cutler facility is situated on approximately 3,000 acres along the Gulf of Maine coast in Cutler, Maine. The facility is composed of three areas: the VLF Peninsula Area, the former Administration and Housing Area, and the HF Area. The former FTA is located on the VLF Peninsula Area, north of the VLF Peninsula, east of the former Salvage Yard Area (SYA) (Site 2), and west of the former Construction Debris Area (Site 3). Undeveloped wooded land is located to the east of the former FTA. The VLF Peninsula is bordered by Machias Bay to the west and Little Machias Bay to the east. Holmes Bay lies west of the Former Administration and Housing Area and HF Area. The location of FTA and DDA is shown on the Project Area Map (**Figure 1-2**).

The area surrounding the NCTAMS LANT Det Cutler facility is mostly rural, with some residential development in the vicinity of the base. Access to the VLF Peninsula Area is restricted by base security and can be gained only through a security checkpoint located in the northeastern portion of the base along Ridge Road. The entrance to the facility is accessed via Ridge Road located approximately 1.5 miles west of Route 191 in Cutler, Maine. While there are no physical access restrictions around the VLF Peninsula, human access to the operational array is prohibited and is restricted to base personnel performing operation and maintenance. Currently, there is no residential or recreational use of the base.

3.6 Ecology

During past removal activities, the removal areas were cleared of vegetation. Upon completion of removal activities, the removal areas were restored by backfilling with appropriate fill and grading

to act as a wetland to match the surrounding terrain. All disturbed areas were subsequently seeded and planted to compliment the surrounding area. The site is not mowed or maintained. Currently the site contains some gravelly areas with low scrub vegetation with trees. A thick layer of vegetation, consisting of herbaceous plants, shrubs, and trees surround the site. Similar vegetative cover was present at the site prior to the remedial activities and is expected to return to the site over time.

During the 2009 soil removal action at the FTA, a wetland area in the central portion of the site was enhanced to augment the wetland restoration area to the north (known as the Sand Wedge Excavation Area) as well as to provide additional habitat for wildlife. The total acreage of the Sand Wedge restored wetland and the enhanced wetlands within the FTA are 3.26 acres (**Figure 3-5**). Forested areas are located around the FTA.

Soil invertebrates such as earthworms are expected to inhabit the terrestrial portion of the site. Standing water may be seasonally present within the wetland; however, fish are not expected to be present within wetlands. Benthic and aquatic invertebrates and amphibians are expected to be found within the wetlands. Birds and mammals such as robin and raccoon are likely to forage on plants and prey items from terrestrial and wetland habitats within the former FTA and elsewhere on the peninsula.

4.0 NATURE AND EXTENT OF CONTAMINATION

Section 4.0 summarizes the soil, sediment, surface water, and groundwater analytical data obtained during environmental investigations and removal actions at the FTA and evaluates the distribution of contaminants at the FTA. Previous sample collection activities occurred from 1991 to 2016 and are summarized in **Section 1.2.3**.

Figure 4-1 depicts the locations of Soil Exposure Area 1, Soil Exposure Area 2, and the wetlands, as well as sample locations for soil, sediment, surface water, and groundwater. Due to the large number of samples located in Soil Exposure Area 2, **Figure 4-2** provides a magnification of Soil Exposure Area 2. In the HHRA discussed later in this report, the evaluation of soil exposure was performed for two soil distinct exposure areas, referred to as Soil Exposure Area 1 and Soil Exposure Area 2 within the FTA site boundaries. In general, Soil Exposure Area 1 (5.56 acres in size) contains lower chemical concentrations, and represents all the soil outside of Soil Exposure Area 2, which is located in the southern portion of the site. Soil Exposure Area 2 (1.45 acres in size) generally contains higher chemical concentrations. The definitions of the exposure areas are described in Section 2.1.1 of the HHRA (presented in **Appendix D**). Figures in **Appendix A** present the historical sample locations in and around Site 1. A tabular summary of all the RI analytical data used in this evaluation is provided in **Appendix B**.

4.1 Project Screening Levels

All RI analytical data results were compared against PSLs to evaluate the nature and extent of contamination. For the FTA, PSLs are based on USEPA Regional Screening Levels (RSLs), USEPA Maximum Contaminant Levels (MCLs), and USEPA and MEDEP surface water criteria. While MEDEP also provides RAGs, they are not applicable to the FTA because the site-specific risk assessments (**Appendix D** and **Appendix E**) will be used to determine the need for remedial action and develop clean-up goals, if required. Furthermore, the selected PSLs are overall more conservative than MEDEP RAGs. Therefore, the selected human health PSLs were used to conservatively evaluate the nature and extent of contamination at the FTA. The ERA (**Appendix E**) provides a detailed evaluation based on ecologically-based screening levels.

The selection of human health PSLs is discussed in detail in Section 3.2.1 of the HHRA (**Appendix D**) and is summarized in the following paragraphs.

Soil PSLs: The USEPA RSL (May 2016 version) for residential soil based on a target excess lifetime cancer risk (ELCR) of 10^{-6} and a target hazard quotient (HQ) of 0.1 was selected for each chemical, as presented in **Table 4-1.**

Sediment PSLs: Published human health screening levels are not available for sediment. Therefore, risk-based screening levels were calculated using the USEPA RSL Calculator in Section 3.2.5 of the HHRA (**Appendix D**), as presented in **Table 4-2**.

Surface Water PSLs: The lowest of the USEPA and MEDEP surface water criteria for the consumption of water and organisms and risk-based screening level calculated using the USEPA RSL Calculator in Section 3.2.4 of the HHRA (**Appendix D**) was selected for each chemical, as presented in **Table 4-4**.

Groundwater PSLs: The lowest of the USEPA MCL, USEPA RSL (May 2016 version) for tap water, and USEPA Vapor Intrusion Screening Level (VISL) for groundwater (May 2016 version) was selected for each chemical, as presented in **Table 4-3**. RSLs and VISLs based on a target ELCR of 10^{-6} and a target HQ of 0.1 were used.

Table 2-1 and **Table 2-2** in **Section 2.0** compare the PSLs with the various soil and groundwater MEDEP RAGs. For soil, the selected PSLs are lower than MEDEP RAGs for 79 of the 97 detected compounds. For groundwater, the selected PSLs are lower than MEDEP RAGs for 41 of the 44 detected compounds. Therefore, the human health PSLs were used to evaluate the nature and extent of contamination at the FTA.

4.2 Data Evaluation

Summary statistics were generated from the soil, sediment, surface water, and groundwater analytical results to provide a numeric summary of the frequency of analyte detections, range of detections, and number of detections above human health PSLs. The numeric summary provides information on the nature and extent of contamination in the FTA. There were no issues with the historical data and all data has been validated.

4.2.1 Sources

The history of the site suggests the sources of contamination include former fire-training activities as well as drum burial. According to a preliminary assessment report completed by the Naval Energy and Environmental Support Activity in 1988, fire-training activities utilized two 4,200-gallon tanks, approximately 8 ft in diameter and 8 ft high in size, that had been cut in half. Waste fuel oil was burned in these tanks. The tanks were partially filled with water before the waste fuel oil was added and ignited. Some of the fuel oil is believed to have been released to the environment due to overfilling or overflow resulting from precipitation (NEESA 1988). According to NCTAMS Fire Department officials, a maximum of 300-400 gallons of waste fuel were burned each year (HMM 1994). Additionally, it was reported that waste No. 6 fuel oil was brought to the FTA and spread on the ground in the early 1980's when base Power Plant engines were switched from No. 6 fuel oil to No. 2 fuel oil.

The DDA, located in the southern portion of the site, was originally identified based on the discovery of a drum in 2006. During previous removal actions, 76 waste oil drums and drum remnants were removed from the DDA.

4.2.2 Soils and Vadose Zone

Surface and subsurface soil samples were collected from 2002 to 2016. Surface and subsurface soil sample locations are shown on **Figure 4-1** and **Figure 4-2**. The frequency of detection, the range of detection, location of the maximum detections, and number of detections above human health PSLs are provided as sitewide summary statistics in **Table 4-1** and **Table 4-2** for surface soil and subsurface soil, respectively.

As shown in **Table 4-1** and **Table 4-2**, Total PCBs (primarily PCB Aroclor-1260), polycyclic aromatic hydrocarbons (PAHs), and metals were frequently detected in soils above the PSLs.

PCB Aroclor-1260 had the highest frequency of detection of the PCB Aroclors. PCB Aroclor-1260 was detected in 103 of 107 surface soil samples and 64 of 114 subsurface soil samples. PCB-contaminated soil was excavated from two areas (PCB Area 1 and PCB Area 2) to a depth of 2-ft (AGVIQ 2015). Confirmation soil samples were collected to verify that the excavation achieved the project-specific removal action goal of 100 milligrams per kilogram (mg/kg) that was used during that effort. The PCB concentrations were less than the 100 mg/kg removal action goal in PCB Area 2 and the eastern side of PCB Area 1. The PCB concentration was greater than the removal action goal at six locations on the western region of PCB Area 1. One ft of soil was excavated from the areas where the PCB concentrations had exceeded the action level and then resampled for PCBs. PCB concentrations at three subsequent confirmation sample locations (PCBAREA1-013 [610 mg/kg], PCBAREA1-011 [240 mg/kg], PCBAREA1-014 [140 mg/kg]) exceeded the PCB removal action goal. Due to funding limitations, further excavation was discontinued and the portion of the excavation containing PCBs greater than the cleanup level was marked with plastic sheeting. PCB Aroclor-1260 results in comparison to human health PSLs are illustrated on **Figure 4-3** for all soil samples. The highest concentrations of PCB Aroclor-1260 were detected in confirmation soil samples located within the 2013 PCB Area 1 excavation conducted by AGVIQ. As illustrated on **Figure 4-3,** the highest PCB Aroclor-1260 soil exceedance (610 mg/kg at PCBAREA1-013) is a sidewall confirmation sample located along the southern wall of the 2013 PCB Area 1.

The highest concentrations of PAHs were identified in surface soil at location FTA-SB-216. Benzo(a)pyrene was detected at a concentration of 4.3 mg/kg at this location. While other samples showed PAH concentrations above human health PSLs, concentrations were much lower, with the next highest benzo(a)pyrene concentration detected at 0.12 mg/kg at location FTA-SB-209. Therefore, it appears that the elevated PAH concentrations in surface soil at location FTA-SB-216, which is located on the western edge of the wetland, are localized and not widespread in soils across the site.

Chromium was detected in surface soil and subsurface soil, but at concentrations less than PSLs. As discussed in **Section 2.4**, during November 2016, 10 soil samples were collected and analyzed for total chromium, hexavalent chromium, and trivalent chromium in order to determine whether chromium present in site media is in hexavalent form. Analytical results from the November 2016 sampling event for total chromium in soil ranged from 18.7 mg/kg to 32.9 mg/kg. Hexavalent chromium was not detected in any soil sample, with DLs ranging from 0.31 mg/kg to 1.6 mg/kg. The residential PSL for hexavalent chromium is 0.3 mg/kg. Even though the DLs exceed the 0.3 mg/kg residential PSL, based on the non-detectable concentrations, it is assumed that hexavalent chromium is not present in soil at the FTA greater than PSLs.

In soil, the frequency of detection was relatively high for various other metals with concentrations above human health PSLs, including aluminum, arsenic, cobalt, iron, manganese, and thallium. Metals concentrations at the FTA were further evaluated in conjunction with the results of the background evaluation (included in **Appendix C**) to determine if they are site-related or non-site-related (i.e., identified as being consistent with background based on a comparison of concentrations in site and background data sets). Aluminum and iron were found to have concentrations in site media less than or consistent with concentrations in site background.

Arsenic was found to have concentrations in site media less than or consistent with concentrations in site background (with the exception of subsurface soil in Soil Exposure Area 2). Cobalt was detected in all 37 of the surface soil samples and 53 of 54 subsurface soil samples in which it was analyzed. Cobalt analytical results exceeded its PSL of 2.3 mg/kg in all soil samples in which it was detected. The highest cobalt surface soil detection (24.2 mg/kg at FTA-SB-201) is located in the northern portion of the site. The highest cobalt subsurface soil detection (20.8 mg/kg at FTA-ANOM1C-SO-INT) is located in the southwestern portion of the site.

Figure 4-4 presents the distribution of manganese concentrations in soil. Manganese was detected in all 37 of the surface soil samples and all 54 subsurface soil samples in which it was analyzed. Manganese analytical results exceeded its PSL of 180 mg/kg in all soil samples. The highest manganese surface soil detection (8,600 mg/kg at FTA-SB-201) is located in the northern portion of the site. The highest manganese subsurface soil detection (1,530 mg/kg at FTA-SB-214) is located in the southwestern portion of the site.

Thallium was detected in all 37 surface soil samples (maximum of 0.14 mg/kg, location FTA-ANOM1E-SO-SURF) and in 52 of the 54 subsurface soil samples (maximum of 0.26 mg/kg, location SB-214) in which it was analyzed. As discussed in **Appendix C**, thallium was not detected in the background soil samples and detection limits were elevated. Therefore, no conclusions were drawn regarding thallium based on the background evaluation.

4.2.3 Groundwater

Groundwater sampling events at the FTA were conducted in 1999, 2007, 2012, 2013, 2014, 2015, and 2016. Groundwater samples were collected during 2014 at 12 existing monitoring well locations at the FTA to confirm previous groundwater conditions. The groundwater samples were collected and analyzed for VOCs, VPH/EPH, and total and dissolved metals. Additionally, groundwater samples were collected in 2012, 2014 and 2015 from the monitoring wells and analyzed for PFASs, as part of the new emerging-contaminant protocol. One groundwater sample collected from monitoring well FTA-MW-208 in November 2016 was analyzed for both total and hexavalent chromium.

Appendix B presents a tabular data summary of all the FTA groundwater analytical results from 1999, 2007, 2012, 2013, 2014, 2015, and 2016. The groundwater results from the 2015 sample event are also submitted in the *Technical Memorandum Evaluation of Groundwater Analytical Results Site 01 – Fire Training Area*. The Technical Memorandum is included in **Appendix F**.

Table 4-3 does not include groundwater data collected before 2012, as the more recent data are more reflective of current conditions. Furthermore, only groundwater data from permanent wells are included. As indicated in USEPA (2014), groundwater data from monitoring wells are preferred over data collected from soil borings and/or temporary well locations, as results for temporary wells may not be reproducible. Therefore, results from the following wells are included in the summary statistics presented in **Table 4-3**:

- FTA-MW-1
- FTA-MW-5
- FTA-MW-9
- FTA-MW-10
- FTA-MW-11
- FTA-MW-12
- FTA-MW-14
- FTA-MW-203
- FTA-MW-206
- FTA-MW-208
- FTA-MW-210
- FTA-MW-218
- DP-35

Historically, the depth to groundwater was shown to decrease from south to north across the site with a decrease in ground elevation. Based on September 2015 monitoring well gauging data, the direction of shallow groundwater flow is generally to the north. A September 2015 groundwater gradient contour map is illustrated on **Figure 3-3**. The hydrograph of groundwater elevation data from 2012 to 2015 (**Figure 3-4**) reveal no discernible patterns in seasonal groundwater flow patterns.

Post-excavation groundwater elevations have not been gauged within the enhanced wetland areas; therefore, it is unknown if the groundwater potentiometric elevations have changed due to the installation of the wetland. However, potentiometric elevations were gauged in wells located outside the wetland areas in 2015, during the monitoring well inspection survey, and potentiometric elevations ranged from approximately 91 ft in the southern portion of the site (MW-208) to approximately 67 ft in the northern portion of the site (MW-14 and MW-11).

4.2.3.1 PCBs

As shown in previous tables, PCBs, primarily PCB Aroclor-1260, were detected in surface soil, subsurface soil, and sediment at the former FTA. However, the groundwater data indicates no detections of PCBs in groundwater at the FTA.

4.2.3.2 PFASs

The groundwater samples from monitoring wells collected in 2012, 2014, and 2015 were also analyzed for PFASs. PFASs are found in some firefighting foams and are considered an emerging contaminant. PFASs have not been investigated at the FTA before 2012; however, it is possible that firefighting foam containing PFASs were used in firefighting activities at the FTA. PFOA and PFOS are fully fluorinated organic compounds and are the two perfluorinated chemicals most commonly found in firefighting reagents. Groundwater samples obtained from wells during the most recent sampling event (September 2015) exhibited the following detected PFOA results: MW-1 (0.015 microgram per liter [µg/L]); MW-210 (0.012 µg/L); DP-35 (0.018 µg/L); MW-14 (0.350 µg/L); MW-5 (0.30 µg/L); MW-9 (0.021 µg/L); MW-11 (0.017 µg/L); MW-10 (0.022 µg/L); and MW-12 (0.0056 µg/L). Groundwater samples obtained from wells in September 2015 exhibited the following detected PFOS results: MW-10 (0.011 µg/L); MW-1 (0.0016 µg/L); MW-9 (0.14 µg/L); MW-11 (0.15 µg/L); and MW-12 (0.011 µg/L). Results from the numerous PFAS sampling efforts have shown that five of the 27 samples exhibited PFOS in excess of the 0.04 µg/L PSL and the USEPA's Lifetime Drinking Water Health Advisory Level (HAL) of 0.07 µg/L (USEPA 2016a) while six of the 27 samples exhibited PFOA in excess of the 0.04 µg/L PSL and the USEPA HAL of 0.07 µg/L (USEPA 2016b). The maximum concentrations of PFOA and PFOS were found in the northern portion of the site (downgradient flow direction of groundwater) in MW-11 in 2014 (0.25 µg/L PFOS) and MW-14 in 2012 (0.45 µg/L PFOA). Both the PSL and the HAL for PFOS are protective of drinking water quality, and not groundwater from monitoring wells.

4.2.3.3 Metals

Concentrations of several metals exceed human health PSLs. Arsenic was detected above the PSL at a maximum concentration of 16 µg/L in MW-5 in September 2015.

Concentrations of total chromium in the permanent wells range from 1.4 µg/L to 26.6 µg/L. The highest concentration of total chromium were identified in the southern portion of the site in MW-208 (26.6 µg/L) in November 2012, however, below the total chromium PSL of 100 µg/L. Upgradient well FTA-MW-208 has exhibited the highest concentrations of total chromium historically and was therefore selected for inclusion in the November 2016 hexavalent chromium sampling event. The results of the speciated chromium sample collected from upgradient well MW-208 in November 2016 indicated a concentration of 5.2 µg/L trivalent chromium and 4.8 µg/L hexavalent chromium, above the PSL for hexavalent chromium of 0.035 µg/L. However, given well MW-208 upgradient location, the results from this well are reflective of background conditions rather than site conditions. Total chromium was not detected in upgradient well FTA-MW-203, and was detected in one sample from upgradient well FTA-MW-218 at a concentration of 4 µg/L.

The maximum concentrations of manganese were found in the northern portion of the site (downgradient flow direction of groundwater) in MW-9, ranging from 3,060 µg/L in June 2014 to 3,850 µg/L in September 2015. Based on the results of the HHRA (**Appendix D**), arsenic and manganese are the most likely risk drivers for a hypothetical future drinking water scenario.

4.2.3.4 VOCs and SVOCs

Other constituents detected above human health PSLs include infrequent detections of SVOCs, including 1,1-biphenyl (four out of 24 samples) and hexachlorocyclopentadiene (one out of 24 samples).

VOCs detected above human health PSLs included: cis-1,2-dichloroethene; trichloroethene; and vinyl chloride. Groundwater samples obtained from MW-206 exhibited the following VOC results in September 2015: trichloroethene (TCE) (10 µg/L); vinyl chloride (0.056 µg/L); and cis-1,2-dichloroethene (cis-DCE) (22 µg/L). Well MW-206 has exhibited consistent concentrations of these three chemicals since 2012. Groundwater samples obtained from downgradient monitoring wells have shown low levels of VOCs, including a maximum vinyl chloride concentration of 0.84 µg/L at MW-9.

4.2.3.5 Total Petroleum Hydrocarbons

Of the total petroleum hydrocarbons (TPH) fractions analyzed, VPH fractions were not detected. The EPH fraction C11-C22 aromatics was detected in MW-5. Potential impacts due to petroleum products are assessed using BTEX and PAH data, and therefore a PSL was not identified.

4.2.4 Surface Water

Surface drainage at Site 1 is assumed to flow towards surrounding wetland areas. Fourteen surface water samples were collected at the FTA during two sampling events in 2012 and 2014. Surface water samples could not be collected from co-located sediment sample locations FTA-SED-05 and FTA-SED-04 in 2014 because no surface water was present at these locations during this sampling event. The surface water samples locations are illustrated on **Figure 4-1**. As shown in **Table 4-4**, the maximum detections were primarily associated with location FTA-SW-06.

Arsenic, manganese, and thallium were the only metals that exceeded the human health PSLs in surface water.

PCB Aroclor-1260 was not detected in any surface water sampling locations during either sampling event. PCB Aroclor-1254 was detected at one surface water sampling location (FTA-SW-06) in 2014 at a concentration of 0.38 µg/L.

Several PAHs were also detected at FTA-SW-06 above the human health PSLs. The highest concentration of PAHs identified at location FTA-SW-06 is indeno(1,2,3-cd)pyrene at a concentration of 0.16 µg/L. Since the PAH exceedances of PSLs are relegated to location FTA-SW-06, it appears that the elevated PAH concentrations in surface water are localized and not widespread across the site.

4.2.5 Sediment

During sampling events conducted in 2012 and 2014, 16 sediment samples were collected. In 2012 and 2014, sediment samples were collected from eight locations (FTA-SED-01 through FTA-SED-08) and analyzed for: Total PCBs, metals, pesticides, TPH, VOCs, and SVOCs. One sediment sample was collected from location FTA-SED-07 in November 2016 and was analyzed for total and hexavalent chromium. The sediment samples were collected from the wetlands portion of the FTA.

The frequency of detection, the range of detection, location of the maximum detections, and number of detections above human health PSLs are provided in **Table 4-5**. The locations of sediment samples are illustrated on **Figure 4-1**.

As shown in **Table 4-5**, PCB Aroclor-1260 was detected in 15 of 16 sediment sampling locations with a maximum concentration of 2.1 mg/kg from FTA-SED-04.

Benzo(a)pyrene was detected in 8 of 16 sediment sampling locations above the PSL, with a maximum concentration of 2.4 mg/kg at location FTA-SED-01.

Arsenic concentrations were detected in all samples and exceeded the sediment PSL of 2.56 mg/kg in 15 of 16 sampling locations. The maximum concentration of arsenic was 19 mg/kg at FTA-SED-04.

Total chromium was detected in wetland sediments at concentrations ranging from 11.3 mg/kg to 33.7 mg/kg. The maximum concentration of total chromium was 33.7 mg/kg at FTA-SED-07. One sediment sample was collected from FTA-SED-07, the location of the maximum detected concentration, and was analyzed for both hexavalent and total chromium. Hexavalent chromium was not detected in this sediment sample. While the DL was elevated due to matrix interference and high moisture content, the DL is an artifact of the sediment matrix and requirements of the analytical method. As discussed in detail in **Appendix G**, multiple lines of reasoning were used to support the weight-of-evidence conclusion that hexavalent chromium is not present at the FTA. Site history, background concentrations, soil characteristics, and laboratory analysis all support the conclusion that hexavalent chromium is not present at the FTA. Therefore, total chromium is evaluated as trivalent chromium, and not hexavalent chromium in sediment, and the PSL based on trivalent chromium is used. Total chromium concentrations are below the sediment PSL of 52,600 mg/kg.

This page intentionally left blank.

5.0 CONSTITUENT FATE AND TRANSPORT

Section 5.0 addresses the persistence and migration characteristics of contaminants identified exceeding the screening criteria and background levels in soil, surface water, sediment, and groundwater media at the FTA as discussed previously in **Section 4.0**. In **Section 5.0**, the characteristics of these contaminants and their transport in the environment are further evaluated. Understanding the fate and transport of constituents is important in evaluating their potential impacts to receptors. The fate and transport of contaminants can occur in all three environmental media: terrestrial (soil and groundwater), aquatic (surface water and sediment), and atmospheric (air). Transport is the simple movement of the constituents, for example, with the flow of groundwater or surface water. Fate is a summary of all the physical and chemical processes that act on the constituents during transport.

5.1 General Fate and Transport Processes of Soil Constituents

The primary route of contaminant migration at the former FTA is via direct release to the ground surface or via drum and debris burial, then infiltration of the contamination into the soil, through the vadose zone and into to groundwater. A secondary route of migration is storm water runoff causing erosion of the contaminated soil at the surface and transport into the nearby drainage features, wetlands and streams. Once the contaminants reach the groundwater under the primary route, the groundwater flow system beneath the former FTA may cause the contaminants to migrate toward and potentially discharge into the downgradient drainage features north of the former FTA. However, historical groundwater sampling at the former FTA indicates that known groundwater plumes are stable or decreasing.

The fate and transport of chemicals in environmental media are affected by a variety of factors, including chemical-specific and medium-specific characteristics. Chemical-specific characteristics are those that are related to the composition and structure of the contaminant, such as solubility, volatility, or the number of functional groups containing hydrocarbons, halogens, oxygen, and nitrogen. These characteristics affect the chemical behavior or reactivity of contaminants, which in turn affect their persistence in the environment. Medium-specific characteristics that affect the fate and transport of contaminants include atmospheric pressure, soil or sediment composition, and groundwater composition. These characteristics affect the physical transport of contaminants by evaporation, sorption, or affect the speciation of certain contaminants.

In order for a chemical to persist in the environment, it must be chemically stable, relative to the biogeochemical conditions to which it is exposed. Chemicals that are inert or do not react under a broad range of conditions are less likely to degrade or be retarded during transport. In addition to a chemical's reactivity, its persistence in the environment may be affected by uptake by various organisms, where it is accumulated or degraded by biological metabolic processes.

Contaminants generally migrate in response to chemical concentration gradients through diffusion processes. They also migrate in conjunction with the movement of solids or fluids in response to an external driving force such as gravity or hydrostatic pressure. The mobility of a contaminant through a specific medium will reflect the combined effects of medium-specific properties, the presence of any anthropomorphic structures, such as underground sewer pipes, and the responses to climatic conditions. Sediments and soils containing high levels of clay and organic matter are more likely to retard the movement of contaminants than sandy materials with low organic contents.

5.2 Site-Specific Fate and Transport

As discussed in **Section 4.0**, Total PCBs (primarily PCB Aroclor-1260), PAHs, and metals in soil; PCB Aroclor-1260, benzo(a)pyrene, arsenic and total chromium in sediment; arsenic, manganese, thallium, PCB Aroclor-1254, and PAHs in surface water; and PFOS, PFOA, arsenic, hexavalent chromium, manganese, PAHs, and chlorinated VOCs (cis-DCE, TCE, and vinyl chloride) in groundwater were identified above PSLs in the environment. The physical and chemical properties and potential release mechanisms and routes of migration for each of these constituent groups are discussed in the following sections.

5.2.1 PCBs

PCBs were detected above PSLs in soils, sediment, and surface water at the former FTA. Wastes gathered at the FTA and DDA have included electrical equipment and drums of waste oils and fluids, which are known to contain PCBs. The PCBs contained within the gathered wastes at the former FTA likely migrated via direct release to the ground surface and via leaking buried drums, followed by infiltration of the contamination into the soil. Sediment and surface water were likely impacted by storm water runoff and erosion of the contaminated soil at the surface and transport into the wetlands.

PCB Aroclors are composed of various combinations of PCBs with different properties such as vapor pressure, solubility, and viscosity. Data for PCBs were primarily available based on PCB Aroclor analysis with a smaller set of samples submitted for analysis of PCB homologues. PCB Aroclor-1260 had the highest frequency of detection of the PCB Aroclors. PCB Aroclor-1260 was detected in 103 of 107 surface soil samples and 64 of 114 subsurface soil samples. PCB Aroclor-1260 was detected in 15 of 16 sediment sampling locations. Total PCBs (as homologues) were detected in one surface water sampling location, and the concentration exceeded the human health-based USEPA National Recommended Water Quality Criteria (NRWQC) and MEDEP surface water criteria.

PCBs belong to a broad family of man-made organic chemicals known as chlorinated hydrocarbons. PCBs were domestically manufactured from 1929 until their manufacture was banned in 1979. They have a range of toxicity and vary in consistency from thin, light-colored liquids to yellow or black

waxy solids. Due to their non-flammability, chemical stability, high boiling point, and electrical-insulating properties, PCBs were used in hundreds of industrial and commercial applications including electrical, heat transfer, and hydraulic equipment; as plasticizers in paints, plastics, and rubber products; in pigments, dyes, and carbonless copy paper; and many other industrial applications. PCBs were principally used as dielectric fluids in electrical transformers and capacitors. The principal source of PCB contamination is typically spillage or leakage of dielectric fluids containing PCBs.

PCB compounds are highly persistent in soil. These compounds demonstrate strong adsorption to soil and sediment media, indicating that significant leaching to groundwater should not occur. PCB compounds may leach into the groundwater when combined with organic solvents, which demonstrate significant leaching capabilities. Adsorption of PCB compounds is elevated by increased organic, clay, and microparticle content of the soil or sediment. Biodegradation can occur under both aerobic and anaerobic conditions, but only at a slow rate. No chemical process is known to degrade PCB compounds in soil. PCBs can biodegrade under anaerobic conditions via dechlorination. The persistence of PCBs at the site is consistent with the strong adsorptive affinities of PCBs for soils. Total PCBs detected in the sediment are also expected to be persistent and may become mobilized from the sediment during erosional processes related to storm events.

5.2.2 Metals

Several metals were detected above PSLs in soil, sediment, surface water and groundwater. Metals are ubiquitous and occur naturally in soil as well as groundwater, sediment and surface water.

Chromium was detected in surface soil and subsurface soil, but at concentrations less than PSLs. As discussed in the hexavalent chromium White Paper (**Appendix G**), the soil characteristics at the site play an important role in the fate of chromium. The overburden materials encountered in the FTA consist generally of medium to coarse sand with lesser amounts of gravel overlying a layer of silty clay. The predominant soil type underlying the FTA is the Pits sand and gravel (USDA NRCS 2016). This soil comprises sediments deposited mainly as glaciofluvial sands and gravels with some glacial till. Soil pH measured for the FTA site indicates that the Pits is an acidic soil. The pH measurements from 19 surface soils collected at the FTA range from 4.5 to 7.1 with the most frequent pH value being 5.4. The acidic soil conditions present at the FTA is not conducive to the presence of chromium in its hexavalent state. Analytical results from the November 2016 sampling event for total chromium in soil ranged from 18.7 mg/kg to 32.9 mg/kg. Hexavalent chromium was not detected in any soil sample, with DLs ranging from 0.31 mg/kg to 1.6 mg/kg. The residential PSL for hexavalent chromium is 0.3 mg/kg. Even though the DLs exceed the 0.3 mg/kg residential PSL, based on the non-detectable concentrations and the soil conditions not conducive to hexavalent chromium, it is assumed that hexavalent chromium is not present in soil at the FTA greater than PSLs.

In soil, the frequency of detection was relatively high for various other metals with concentrations above human health PSLs, including aluminum, arsenic, cobalt, iron, and manganese. Aluminum and iron were found to have concentrations in site media less than or consistent with concentrations in site background. Arsenic was found to have concentrations in site media less than or consistent with concentrations in site background.

In sediment, arsenic exceeded the human health PSL. In surface water, arsenic, manganese, and thallium were the only metals that exceeded the human health PSLs. In groundwater, concentrations of total chromium in the permanent wells range from 1.4 µg/L to 26.6 µg/L. The highest concentration of total chromium were identified in the southern portion of the site in MW-208 (26.6 µg/L) in November 2012, however, below the total chromium PSL of 100 µg/L. The November 2016 results for FTA-MW-208 indicated that total chromium was detected at a concentration of 9.97 µg/L and hexavalent chromium was detected at a concentration of 4.8 µg/L, above the PSL of 0.035 µg/L for hexavalent chromium. However, given well MW-208 upgradient location, the results from this well are reflective of background conditions rather than site conditions. Concentrations of several metals exceed human health PSLs. Arsenic was detected above the PSL at a maximum concentration of 16 µg/L in MW-5 in September 2015. The maximum concentrations of manganese were found in the northern portion of the site (downgradient flow direction of groundwater) in MW-9, ranging from 3,060 µg/L in June 2014 to 3,850 µg/L in September 2015.

There are no reported uses of chromium or other metals at the FTA in a manufacturing process or primary waste storage or disposal. The FTA is an abandoned gravel pit that was historically used for fire-training exercises from the 1960s through the 1980s and disposal of waste fuel oil and drum disposal. Buried drums were removed from the site and residual PCB contamination was identified. From 1999 to 2013, approximately 1.8 million gallons of water were pumped and treated and approximately 40,326 tons of soil have been removed from the FTA during the historical removal actions at the site. These actions would have also resulted in a reduction of site metals concentrations at the site. Based on the historical removal actions at the site and the data that show the remaining site soil metals concentrations are similar to site background levels, no release of metals to site media (including soil, groundwater, sediment and surface water) due to site activities is indicated.

5.2.3 PAHs

PAHs at the former FTA could be the result of burning of waste oils during fire training activities and were likely contained within buried drums of waste oil. However, PAHs, including benzo(a)pyrene, are anthropogenic compounds that are found in man-made sources and are persistent in the environment. PAHs also occur naturally. PAHs are present in oil, coal, and tar deposits and in asphalt pavement. They are also found in terrestrial and aquatic plants, in soils and

bottom sediments, in fresh and marine waters, and in natural deposits of peat as well as emissions from forest fires. Their presence at the FTA in soils is consistent with their slow environmental degradation.

PAHs are persistent and generally immobile in soil matrices under normal environmental conditions. PAHs are hydrophobic, and their persistence in the environment is mainly due to their chemical stability and low water solubilities. In general, the solubility of the PAHs decreases as the molecular weight increases. High-molecular-weight PAHs have higher hydrophobicity and tend to persist in environmental media. Their transport may be enabled by the presence of organic colloids or bacterial materials. Low-molecular-weight PAHs (e.g., naphthalene) volatilize more easily.

The PAHs tend to bioaccumulate because they are non-polar. In surface water, PAHs tend to sorb to particles that either have settled to the bottom or are suspended in the water column. These high-molecular-weight PAHs appear to have lower settling fluxes and tend to be buried in sediment layers. Biodegradation rates decrease with increasing molecular weight. PAHs can be reduced through microbial metabolism. In soil, PAHs tend to degrade because of microbial metabolism. The rate of degradation is dependent upon factors such as temperature, pH, oxygen availability, soil type, contaminants present, and PAH concentrations.

The highest concentrations of PAHs were identified in surface soil at location FTA-SB-216. Benzo(a)pyrene was detected at a concentration of 4.3 mg/kg at this location. While other samples showed PAH concentrations above human health PSLs, concentrations were much lower, with the next highest benzo(a)pyrene concentration detected at 0.12 mg/kg at location FTA-SB-209. Therefore, it appears that the elevated PAH concentrations in surface soil at location FTA-SB-216, which is located on the western edge of the wetland, are localized and not widespread in soils across the site. In groundwater, PAHs were detected above human health PSLs infrequently. Additionally, their maximum detection in wells MW-5 and MW-10, which are located in the vicinity of the site near the subsurface peat deposits, indicates the peat may be acting as a natural source of the PAHs. Since the PAH exceedances of PSLs are infrequent and the maximum detections are located near the peat deposits, no potential release of PAHs to groundwater from site activities is indicated.

In surface water, several PAH detections above the human health PSLs were relegated to FTA-SW-06. Since the PAH exceedances of PSLs are relegated to location FTA-SW-06, it appears that the elevated PAH concentrations in surface water are localized and not widespread across the site. Because of the localized elevated PAH concentrations, no release of PAHs to surface water from site activities is indicated.

Benzo(a)pyrene was detected in 8 of 16 sediment sampling locations above the PSL, with a maximum concentration of 2.4 mg/kg at location FTA-SED-01. Benzo(a)pyrene was also detected in

soil at the FTA. The highest concentrations of PAHs were identified in surface soil at location FTA-SB-216 at a concentration of 4.6 mg/kg.

5.2.4 VOCs

VOCs at the former FTA are possibly the result of the use of combustible chlorinated solvents during fire-training activities and were possibly contained within buried drums. The VOC-containing solvents would have been spilled onto the ground surface and then infiltrated into the soil and into groundwater. The VOC detection pattern at the FTA is consistent with the characteristic environmental behavior of chlorinated solvents. Commonly, chlorinated solvents, when released to the environment (e.g., surface spills, historic disposal practices), will migrate downward through the soil matrix to the groundwater under density-driven flow, provided that the contaminant mass is sufficient to overcome pore throat entry pressure and the retardation properties of the soil matrix.

Chlorinated VOCs are generally mobile in the environment, primarily due to their high volatility, low adsorption to some soils, and low to high aqueous solubilities. They are relatively persistent in the environment because they do not degrade very easily under oxidizing conditions and therefore are not easily degraded by bacteria or taken up by other organisms in these environments. Chlorinated aliphatics, such as cis-DCE, TCE, and vinyl chloride, have been observed in groundwater at the former FTA. These hydrocarbons have variable solubilities and may be carried for some distance in groundwater. Because of these characteristics, the primary fate and transport mechanisms affecting VOCs are volatilization into the air and migration in groundwater. The high volatility of VOCs somewhat limits the extent to which surface water or groundwater transport will be a major transport process, because VOCs may volatilize out of unconfined or partially confined aquifers. Due to the high mobility of VOCs, a decrease in their concentrations is anticipated with time, as long as there is no additional input of these compounds.

Chlorinated VOCs also tend to undergo degradation reactions in anaerobic soil systems (reducing environments). The degradation reactions involve the progressive loss of chlorine ions from the molecular structure, resulting in a stepwise dechlorination under reducing conditions. An oxidizing environment would not favor large-scale reductive degradation of the TCE/cis-DCE/vinyl chloride series of compounds. However, some of the elevated metals data suggest the groundwater flow system is more reducing in some areas of the FTA.

5.2.5 PFASs

PFASs at the former FTA were likely contained within the firefighting foam used in firefighting activities. Given the numerous soil removal actions at the FTA, it is unlikely that remaining soils contain PFASs. PFASs are compounds used in the formulation of firefighting foam. PFOA and PFOS are fully fluorinated organic compounds and are the two perfluorinated chemicals most commonly

found in firefighting reagents. These emerging contaminants have unique chemistry due to carbon-fluorine bonds, which are the strongest bonds in nature.

There are many different factors that can influence the fate and transport of PFASs. This is especially true when PFASs are co-mingled with hydrocarbon fuels as is often the case at FTAs. When hydrocarbon fuels are released, indigenous microorganisms rapidly biodegrade/oxidize the fuels resulting in anaerobic conditions (i.e., negative redox) at the source area. Firefighting foam contains long chain fluorotelomer alcohols that will also biodegrade and further reduce the redox conditions in source areas. This biodegradation will dead end at eight carbon compounds including PFOS and PFOA, which have not been shown to be aerobically or anaerobically biodegradable. Some of these long chain fluorotelomer alcohols will not biodegrade in the source area and will migrate downgradient until the fuels attenuate and the natural aerobic conditions prevail. These aerobic conditions will result in biodegradation of the fluorotelomer alcohols and result in increasing concentrations of PFOS and PFOA farther downgradient. An increase in concentrations can be incorrectly interpreted as another source area. Results from the PFC sampling efforts have shown that the maximum concentrations of PFOA and PFOS were found in the northern portion of the site (downgradient flow direction of groundwater) in MW-11 and MW-14.

5.2.6 TPH

TPH compounds represent a complex mixture of EPH and VPH ranges of aliphatic or aromatic hydrocarbons. TPH compounds at the former FTA are likely the result of the burning of petroleum waste oils during fire training activities and are likely contained within buried drums of waste oil. The waste oils would have been spilled onto the ground surface and then infiltrated into the soil and into groundwater. Residual petroleum hydrocarbons are typically contained in the soil and do not readily move, but can continue to act as a remaining source for groundwater contamination.

As described **Appendix A**, approximately 20,000 tons of petroleum-contaminated soil were removed and treated at the site in 2006 and 2008. Of the TPH fractions analyzed, VPH fractions were not detected in groundwater. The EPH fraction C11-C22 aromatics was detected in MW-5 only. The limited TPH detections in groundwater are consistent with the characteristic that, after a petroleum release, the bulk of the hydrocarbon remained as residual material adsorbed to soil particles or accumulated between soil particle pore space at the site, with a small percentage of the petroleum hydrocarbon mass dissolving into the aqueous phase.

The past excavation efforts at the site resulted in the removal of remaining soil sources of petroleum groundwater contamination and have resulted in limited TPH groundwater contamination.

This page intentionally left blank.

6.0 BASELINE RISK ASSESSMENT

Section 6.0 discusses the baseline risk assessment.

6.1 Human Health Evaluation

The HHRA was conducted in accordance with *Navy Policy for Conducting Human Health Risk Assessments* (DON 2001), *Navy Human Health Risk Assessment Guidance* (DON 2008), *USEPA Risk Assessment Guidance for Superfund* (USEPA 1989), and MEDEP risk assessment guidance (MEDEP 2011), as referenced in the complete HHRA report attached as **Appendix D**. The tiers of evaluation that were followed to conduct the HHRA were the Tier IA Human Health Risk-Based Screening Evaluation and the Tier II Baseline HHRA.

The HHRA approach used in the HHRA generally follows the approach used for evaluation of the Site 4/VLF Peninsula risk assessment (Resolution 2016a) and the Site 2/SYA risk assessment (Resolution 2016b) to provide consistency in the HHRA approach between multiple sites within NCTAMS LANT Det Cutler.

The primary objective of the HHRA is to evaluate whether exposure to COPCs attributable to past operations at the FTA may pose a risk to human health above USEPA or MEDEP target levels. The evaluation focuses on quantitative estimation of current and potential future risks and hazards to current and potential future human receptors that may come into contact with site-related chemicals in soil, groundwater, air, sediment, and surface water at the former FTA.

6.1.1 Data Evaluation and Hazard Identification

The analytical data set evaluated in the HHRA is described in detail in Section 2.0 of the HHRA (**Appendix D**). The Hazard Identification and selection of COPCs for evaluation in the HHRA is described in Section 3.2 of the HHRA (**Appendix D**).

6.1.1.1 Soil

Soil samples were collected during multiple sampling events conducted between 2002 and 2016 from various depth intervals between the ground surface and 10 ft bgs. Samples identified as removed during excavations were not included in the HHRA. For the purposes of the HHRA, and for consistency with the VLF Peninsula/SYA HHRAs (Resolution 2016b, 2017) surface soil is defined as soil collected within the 0–2 ft depth interval and subsurface soil is defined as soil collected within the depth interval ranging from >2 to 15 ft bgs.

Soil exposure areas were defined based on a review of analytical data and the spatial distribution of key COPCs, primarily Total PCBs and secondarily PAHs. **Figure 4-3** spatially depicts concentrations of PCB Aroclor-1260. Significant remediation has been conducted on the northern portion of the former FTA, historically used for firefighting training. Chemical concentrations are generally lower than in the more southern portion of the site, historically used for drum disposal. Therefore, the

evaluation of soil exposure in the HHRA was performed for two soil distinct exposure areas, referred to as Soil Exposure Area 1 and Soil Exposure Area 2 within the FTA site boundaries. In general, Soil Exposure Area 1 (5.56 acres in size) contains lower COPC concentrations, and represents all the soil outside of Soil Exposure Area 2. Soil Exposure Area 2 (1.45 acres in size) generally contains higher COPC concentrations. The definitions of the exposure areas are described in Section 2.1.1 of the HHRA (presented in **Appendix D**). The wetlands (3.26 acres) were not included in the soil exposure areas, which were treated as one exposure area for sediment and surface water.

Soil COPCs were selected for evaluation in the HHRA based on the PSLs described in **Section 4.1**, and are PCBs, PAHs, pesticides, and metals.

Figure 4-1 depicts the locations of Soil Exposure Area 1, Soil Exposure Area 2, and the wetlands.

6.1.1.2 Groundwater

Groundwater samples were collected during multiple sampling events conducted between 1999 and 2016. The hydrograph of groundwater elevation data from 2012 to 2015 (**Figure 3-4**) reveals no discernible patterns in seasonal groundwater flow. Therefore, the use of multiple rounds of data from the same well is appropriate for this HHRA. The latest two rounds of sampling include June 2014 and June 2015 (with one additional round included at FTA-MW-206 in September 2013 for PCBs, pesticides, SVOCs, and VOCs, and one additional round included at FTA-MW-208 in November 2016 for total and hexavalent chromium only). However, because the 2014 and 2015 rounds had slightly varying analyte lists for SVOCs and VOCs, the November 2012 round was included to ensure adequate data points per chemical and well. Groundwater data collected before 2012 were not used in the HHRA, as the more recent data are more reflective of current conditions.

Based on September 2015 monitoring well gauging data, the direction of shallow groundwater flow, in the surficial materials, is generally to the north toward the wetland area. FTA-MW-203, FTA-MW-208, and FTA-MW-218 are located hydraulically upgradient from the wetland area and distant from any site-related activities. With the exception of a very low level detection of PFOA in FTA-MW-218, only inorganics were detected in these wells, suggesting the wells are not site impacted and more consistent with upgradient conditions. The PFOA detection is an estimated concentration at or near the DL and below the PSL, and likely represents a sampling artifact rather than a site-related condition. Therefore, these three upgradient wells were not included in the HHRA. The permanent groundwater wells included in the HHRA are listed as follows:

- FTA-MW-1
- FTA-MW-5
- FTA-MW-9

- FTA-MW-10
- FTA-MW-11
- FTA-MW-12
- FTA-MW-14
- FTA-MW-206
- FTA-MW-210
- DP-35

Groundwater COPCs were selected for evaluation in the HHRA based on the PSLs described in **Section 4.0**, and include PFOS, PFOA, select SVOCs, and VOCs, and metals.

6.1.1.3 Surface Water and Sediment

The total acreage of the Sand Wedge restored wetland (0.44 acres) and the enhanced wetland (2.84 acres) within the FTA is 3.26 acres. Both the restored wetland (also known as the Sand Wedge) and the enhanced wetland were evaluated as one exposure area for both surface water and sediment.

Surface water and sediment COPCs were selected for evaluation in the HHRA based on the PSLs described in **Section 4.1**, and are PCBs, PAHs, and metals.

6.1.2 Exposure Assessment

Currently, the FTA is unused and undeveloped open space. While there are no physical access restrictions to the FTA, human access to the area is prohibited and is restricted to Cutler base personnel performing operation and maintenance. Currently, there is no residential or recreational use, and children are not permitted to access the FTA. Access to the peninsula is restricted by base security and can only be gained through a security checkpoint located in the northern portion of the base along Ridge Road. The entrance to the NCTAMS LANT Det Cutler is accessed via Ridge Road located approximately 1.5 miles west of Route 191 in Cutler, Maine (Tetra Tech 2010). There are currently no future redevelopment plans.

For the purposes of the HHRA, it was conservatively assumed that humans may trespass onto the site under current conditions. Currently, there are no workers at the FTA, although a construction worker is assumed to be potentially exposed under the current and future scenario. The FTA is not regularly maintained and there are no activities occurring in the area. Future land use of the site is likely to remain constant into the future. However, it was conservatively assumed that future receptors may include industrial workers and residents under a hypothetical scenario in which the area is redeveloped for regular commercial/industrial and/or residential use. While no residential

development is planned for the site, this unlikely future scenario was evaluated in the HHRA to provide useful information for decision-making purposes (e.g., implementation of land use restrictions or remedial activities).

Based on the information discussed previously, the following receptors and potential exposure pathways were evaluated in the HHRA:

- Current/Future Construction Worker
  - Exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air.
  - Exposure to groundwater in an excavation trench through incidental ingestion, dermal contact, and inhalation of volatiles in air within the trench.
  - Exposure to surface water and sediment through incidental ingestion and dermal contact.
- Current/Future On-Site Recreational User/Trespasser
  - Exposure to surface soil (current/future) or subsurface soil (future) through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air (current/future use scenario).
  - Exposure to surface water and sediment through incidental ingestion and dermal contact.
- Future Outdoor Industrial Worker
  - Exposure to surface soil (current/future) or subsurface soil (future) through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air (current/future use scenario).
- Future Indoor Industrial Worker
  - Exposure to indoor air via volatilization from groundwater (i.e., vapor intrusion).
- Hypothetical Future On-Site Resident
  - Exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air.
  - Exposure to groundwater through ingestion of drinking water and dermal contact and inhalation during bathing/showering.

- Exposure to indoor air via volatilization from groundwater (i.e., vapor intrusion).
- Exposure to surface water and sediment through incidental ingestion and dermal contact.

The HHRA evaluated all receptors for both a reasonable maximum exposure (RME) and central tendency exposure (CTE) scenarios.

As noted previously, the site has been divided into two areas for the evaluation of soil: Soil Exposure Area 1 and Soil Exposure Area 2 (**Figure 4-1**). Under a hypothetical future use exposure scenario, the site could be developed for residential use, where the site may be divided into separate residential lots. The area of a typical residential lot is considered to be a minimum of 0.5 acre, especially given the rural nature of Cutler. While chemical concentrations between the two areas are different (Soil Exposure Area 1 has lower concentrations), the chemical concentrations within each exposure area are relatively consistent; therefore, exposure is expected to be similar regardless of how the areas could be subdivided in the future. With the exception of the construction worker, receptors are assumed to be exposed to surface soil only (the construction worker is assumed to be exposed to both surface and subsurface soil). However, under future conditions, redevelopment could result in mixing of surface and subsurface soil, or re-grading, potentially exposing subsurface soil as surface soil. Given the uncertainty surrounding hypothetical future mixing and/or grading of site soils, two future scenarios were evaluated, one in which receptors are potentially exposed to current surface soil and one in which receptors are potentially exposed to current subsurface soils.

Exposure to groundwater COPCs was evaluated based on permanent monitoring well data collected between 2012 and 2016. Under a hypothetical future use scenario, it is assumed that a private potable well may be installed for residential use anywhere on the site. Similarly, it is assumed that under a hypothetical future use scenario, a residential or commercial/industrial building may be constructed anywhere on the site, in which volatiles in groundwater may potentially migrate to overlying indoor air.

In addition, it is assumed that construction/excavation-type activities may be performed anywhere on the site. Based on September 2015 water level data from 26 site monitoring wells, the depth to groundwater ranges from less than 0.5 ft to approximately 13 ft bgs. Given the relatively shallow groundwater present, it was assumed that a construction worker may contact groundwater during construction/excavation-type activities.

Standing water may be seasonally present within the wetland area; however, fish suitable for human consumption are not expected to be present. Maximum water depths during the 2014 wetland sampling effort were approximately 6 inches with no standing water present at some

locations. Therefore, any activities involving surface water (e.g., wading) are expected to be minimal. Nonetheless, both surface water and sediment exposure are conservatively evaluated in the HHRA.

6.1.3 Toxicity Assessment

The toxicity assessment was conducted in accordance with USEPA guidance and considers chronic (long-term) and subchronic (fewer than 7 years) exposures for both carcinogenic and noncarcinogenic COPCs. Toxicity values were selected in accordance with USEPA's hierarchy of sources.

6.1.4 Risk Characterization

Appendix D, Tables 11.1 (RME and CTE) through 11.5 (RME and CTE) provide summaries of potential ELCRs and noncarcinogenic HIs for the exposure pathways evaluated. Potential ELCRs and HIs above MEDEP or USEPA target levels are identified separately to facilitate risk management decisions. **Appendix D**, Tables 11.1 (RME and CTE) through 11.5 (RME and CTE) also list the chemicals identified as risk drivers for each exposure scenario in which the total potential ELCR or total potential HI are above MEDEP target levels (i.e., total ELCR > 10^{-5}, and total HI > 1 per target endpoint), as requested by MEDEP (Tetra Tech 2014). For each associated exposure pathway (scenario [i.e., RME or CTE]/receptor/medium) with a potential risk/HI above MEDEP target levels, risk drivers were defined as COPCs with an individual ELCR > 10^{-6} or target organ HI > 1.

Summary tables showing the total receptor ELCRs and HIs for risk drivers only are presented in **Appendix D** (Tables 10.1.RME/CTE through 10.5.RME/CTE). The identified risk drivers were further evaluated in conjunction with the results of the background evaluation (included as **Appendix C** and described in **Section 2.4**) to determine if they are site-related or non-site-related (i.e., identified as being consistent with background based on a comparison of concentrations in site and background data sets). The following risk drivers identified based on the HHRA results were found to have concentrations in site media less than or consistent with concentrations in background and are therefore not considered site-related COCs for the FTA:

- Soil Exposure Area 1
  - *Surface Soil:* Arsenic
  - *Subsurface Soil:* Arsenic
- Soil Exposure Area 2
  - *Surface Soil:* Arsenic

An overall summary of potential ELCR and HI results for the receptors evaluated at the former FTA is presented in **Appendix D**, Tables 11.1 (RME and CTE) through 11.5 (RME and CTE). A summary

of the HHRA conclusions by each receptor group, including a summary of the risk drivers, is presented as follows.

6.1.4.1 Current/Future Construction Worker

A current/future construction worker was evaluated for exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air; groundwater through incidental ingestion, dermal contact, and inhalation of volatiles in an excavation trench; and exposure to surface water and sediment in the wetland area through incidental ingestion and dermal contact. Potential soil exposure scenarios were evaluated on an exposure area basis. Potential groundwater exposure scenarios were evaluated based on exposure point concentrations (EPCs) developed for the wells listed in **Section 6.1.1.2**. Both the restored wetland and enhanced wetland were evaluated as one exposure area for both surface water and sediment.

All total ELCRs for the RME and CTE current/future construction worker are within USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Therefore, no risk drivers are identified based on potential carcinogenic risk utilizing USEPA guidance or MEDEP guidance.

Target organ HIs are greater than MEDEP's and/or USEPA and MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- Soil Exposure Area 1
  - *Surface Soil:* Manganese (RME and CTE)
  - *Subsurface Soil:* Manganese (RME and CTE)
- Soil Exposure Area 2
  - Surface Soil: Manganese and Total PCBs (RME only)
  - *Subsurface Soil:* Manganese (RME and CTE)

6.1.4.2 Current/Future On-Site Recreational User/Trespasser

A current/future on-site recreational user (adult/child) was evaluated for exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air; and exposure to surface water and sediment in the wetland area through incidental ingestion and dermal contact. Potential soil exposure was evaluated on an exposure area basis.

The total ELCRs for the RME and CTE current/future recreational user/trespasser are within USEPA's target ELCR range of 10^{-6} to 10^{-4}. Therefore, no risk drivers are identified based on potential carcinogenic risk utilizing USEPA guidance.

Total ELCRs/HIs are above MEDEP's target ELCR of 10^{-5} and/or USEPA and MEDEP's target HI of 1 within the following exposure areas and media based on the following risk drivers:

- Soil Exposure Area 2
  - *Surface Soil:* Total PCBs (RME and CTE), and benzo(a)pyrene, (RME only)

6.1.4.3 Future Outdoor Industrial Worker

A future outdoor industrial worker was evaluated for exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air on an exposure area basis.

The total ELCRs for the RME and CTE future outdoor industrial worker are below or within USEPA's target ELCR range of 10^{-6} to 10^{-4}. Therefore, no risk drivers are identified based on potential carcinogenic risk utilizing USEPA guidance.

Total ELCRs/HIs are above MEDEP's target ELCR of 10^{-5} and/or USEPA and MEDEP's target HI of 1 within the following exposure areas and media based on the following risk drivers:

- Soil Exposure Area 2
  - *Surface Soil:* Total PCBs (RME only)

6.1.4.4 Future Indoor Industrial Worker

A future indoor industrial worker was evaluated for exposure to volatiles in groundwater via the vapor intrusion pathway. Potential exposure for this scenario was evaluated assuming a commercial/industrial building may be constructed anywhere on site under a hypothetical future use scenario.

The total potential ELCRs for the RME and CTE future indoor industrial worker are below USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Total potential HIs are below USEPA/MEDEP's target HI of 1. Therefore, no risk drivers are identified for the future industrial indoor worker.

6.1.4.5 Hypothetical Future On-Site Resident

A hypothetical future on-site resident was evaluated for exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air; exposure to volatiles in groundwater via showering/bathing and in indoor air via the vapor intrusion pathway; and exposure to surface water and sediment in the wetland area through incidental ingestion and dermal contact. Potential soil exposure scenarios were evaluated on an exposure area basis. Potential groundwater exposure scenarios were evaluated based on EPCs developed for wells listed in **Section 6.1.1.2**. The restored and enhanced wetland was

evaluated as one exposure area for both surface water and sediment. It is assumed that a residence may be constructed anywhere on the site and/or a private potable well may be installed for residential use anywhere on the site under a hypothetical future use scenario.

Total ELCRs are above MEDEP's target ELCR of 10^{-5} and/or above USEPA/MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- Soil Exposure Area 2
  - *Surface Soil:* Total PCBs (RME and CTE) and benzo(a)pyrene, (RME only)
  - *Subsurface Soil:* Total PCBs (RME and CTE) and arsenic (RME only)
- Groundwater
  - Trichloroethene, vinyl chloride, arsenic, and manganese (RME and CTE)

6.1.5 Uncertainty Assessment

Estimation of potential risks to human health that may result from exposure to chemicals in the environment is a complex process that often requires the combined efforts of multiple disciplines. Each assumption, whether regarding the toxicity value to use for a particular chemical or the value of a parameter in an exposure equation, has a degree of variability and uncertainty associated with it. In each step of the risk assessment process, beginning with the data collection and analysis, and continuing through the toxicity assessment, exposure assessment, and risk characterization, conservative assumptions are made that are intended to be protective of human health and to ensure that risks are not underestimated. There is a probability of overestimating health risks or hazards for a number of reasons. The HHRA (included as **Appendix D**) provides a discussion of the key uncertainties that may affect the final estimates of human health risk in this HHRA.

6.1.6 HHRA Conclusions

The HHRA results (included in **Appendix D**) identified the following risk drivers not attributable to background for one or more receptors/exposure areas:

- Surface Soil
  - *Soil Exposure Area 1:* Manganese
  - *Soil Exposure Area 2:* Manganese, benzo(a)pyrene, and Total PCBs
- Subsurface Soil
  - *Soil Exposure Area 1:* Manganese
  - *Soil Exposure Area 2:* Arsenic, manganese, and Total PCBs

- Groundwater (hypothetical future drinking water scenario)
  - Arsenic
  - Manganese
  - Trichloroethene
  - Vinyl chloride

6.2 Ecological Risk Assessment

The ERA was conducted in accordance with *Navy Policy for Conducting Ecological Risk Assessments* and *Navy Guidance for Conducting Ecological Risk Assessments* (DON 1999a,b). The complete risk assessment approach, with data tables and figures, is included as **Appendix E**. The approach was consistent with the eight-step tiered approach presented in *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments, Interim Final* (USEPA 1997). As described in Navy guidance (DON 1999a,b), a tiered approach that incorporates different levels of assessment complexity is used to evaluate the potential for ecological risk. The tiered approach may be implemented in its entirety depending on the level and magnitude of risk that is determined in prior tiers.

The Tier 1 ecological Screening Risk Assessment (SRA) is being submitted with the RI report for regulatory review. Based on the results of the Tier 1 ecological SRA, a preliminary Tier 2, Step 3a Baseline ERA (BERA) was prepared to further assess the potential for adverse effects to ecological receptors associated with the former FTA. The Tier 2, Step 3a evaluation is frequently a free-standing evaluation conducted following agency review of the Tier 1 ecological SRA scientific/management decision point. However, in this instance, the approach for the evaluation of ecological risks included a refined evaluation to be included in Step 3a.

The approach for the ERA follows the approach used recently for the VLF Peninsula and SYA ERAs (Resolution 2016a,b). An ERA Work Plan was not generated for the former FTA, but the 2012 Tier II Sampling and Analysis Plan for the former FTA (Tetra Tech 2012) identified ecological screening levels and relevant exposure pathways that were similar to those considered at the SYA; both areas included terrestrial and wetland habitats.

The primary objective of the ERA for the former FTA was to evaluate the potential for ecological risks associated with the historic use of the area for firefighting operations and disposal of fuel oil. The ERA focuses on surface soil, surface water, and sediment exposure pathways. Chemicals in surface soil may be contacted directly by plants and invertebrates living in the soil. Chemicals in sediment and surface water may be contacted directly by aquatic or benthic invertebrates living in the wetland. Wildlife foraging within the former FTA could also be exposed directly to chemicals in

soil, surface water, and sediment through incidental ingestion of soil, surface water, and sediment and/or indirectly by ingestion of contaminated prey items living at the Site.

Environmental data used in the ERA include surface soil, freshwater sediment, and freshwater surface water collected between 2006 and 2016. The analytical data set considered in the ERA is described in more detail in Section 2 of **Appendix E** and the data are included in Attachment A of **Appendix E**.

The following sub-sections summarize the findings of the Tier 1 ecological SRA, the Tier 2, Step 3a evaluation, the uncertainties associated with the ERA, and the conclusions of the ERA. The ERA is presented in **Appendix E**.

6.2.1 Tier 1 Ecological Screening Risk Assessment

The primary objective of a Tier 1 ecological SRA is to determine which, if any, exposure pathways and COPCs warrant further evaluation in a more refined ERA. The SRA included comparisons of maximum detected concentrations of chemicals against conservative media-specific benchmarks and food web modeling using conservative assumptions to assess whether further evaluation was warranted for any exposure pathways and COPCs. The SRA evaluated the following exposure areas, receptors, and media:

- *Surface Soil (0–2 ft horizon):* Evaluated for potential risks to plants, soil invertebrates, birds, and mammals in the terrestrial portions of the former FTA.
- *Freshwater Surface Sediment (0–0.5 ft horizon):* Evaluated for potential risks to freshwater benthic invertebrates, birds, and mammals in the wetlands of the former FTA.
- *Freshwater Surface Water:* Evaluated for potential risks to the aquatic community, birds, and mammals in the wetlands of the former FTA.

Section 3.3 of **Appendix E** presents the conclusions and recommendations for the SRA. The Tier 1 ecological SRA concluded that certain metals, pesticides, SVOCs, VOCs, and Total PCBs may pose a potential risk to plants, invertebrates, and/or wildlife. As described in Section 3.5 of **Appendix E**, based on the results of the Tier 1 ecological SRA, a Tier 2, Step 3a BERA was prepared to further assess the potential for adverse effects to ecological receptors associated with the former FTA.

6.2.2 Tier 2 Baseline Ecological Risk Assessment

The purpose of Tier 2, Step 3a is to reevaluate COPCs that were retained in the SRA and to identify and eliminate from further consideration those COPCs that were retained because of the use of very conservative exposure scenarios. Using less conservative but more realistic Tier 2, Step 3a assumptions, the Tier 1 ecological SRA risk estimates were recalculated for the pathways and COPCs retained at the end of the Tier 1 ecological SRA.

Refinements included in the Tier 2, Step 3a evaluation included the use of the upper confidence limit (UCL) on the arithmetic mean (instead of the maximum concentrations) and means as EPCs, the use of alternate media-specific benchmarks, the use of refined exposure parameters for birds and mammals, and consideration of Site media concentrations in the context of background conditions.

The results of the Tier 2, Step 3a evaluation are summarized in the following sections, and details are provided in the ERA included as **Appendix E**. Section 4.3 of **Appendix E** describes the refinements included in the Tier 2, Step 3a evaluation and Section 4.4 presents the refined risk calculations. Section 4.5 discusses uncertainties in the evaluation, Section 4.6 presents the risk characterization discussion, and Section 4.7 summarizes the results of the ERA.

6.2.2.1 Terrestrial Plants and Soil Invertebrates

The potential for risks to terrestrial plants and soil invertebrates was evaluated by comparing soil EPCs against benchmarks and identifying COPCs that are consistent with background. Due to the conservative nature of the benchmarks, a review of the basis of the toxicity information behind the benchmarks was also conducted to assess whether the benchmarks were overly conservative.

The benchmark comparisons in the Tier 2, Step 3a evaluation indicated the potential for risks to terrestrial plants or soil invertebrates due to manganese, selenium, vanadium, nine pesticides, four SVOCs, two VOCs, and Total PCBs using the refined maximum EPC; however, there are significant uncertainties about the true bioavailability and toxicity of these COPCs to plants and invertebrates. In addition, three of the organic COPCs (endrin aldehyde, carbazole, and dibenzofuran) were infrequently detected and selenium and vanadium were consistent with background; therefore, these COPCs can be eliminated from further evaluation. Risks due to the remaining pesticides and other organic COPCs are likely overestimated due to the conservative nature of the benchmarks and/or the limited number of detected concentrations.

Potential manganese risks to plants and invertebrates cannot be ruled out based on background or the alternate toxicity value review. However, given the relatively low magnitude of the exceedances relative to the alternate toxicity values, the infrequency of the exceedances, and the much lower manganese concentrations in sediments of the nearby restored Sand Wedge wetland, it is expected that risks to plants and soil invertebrates are overestimated and not sufficient to warrant carrying manganese further in the ERA process.

6.2.2.2 Wildlife in Terrestrial Exposure Areas

The terrestrial food web models identified HQs above 1 for the American robin and the short-tailed shrew for several COPCs. The models used to evaluate these receptors may overestimate potential risks because they assume that the receptors are only foraging on soil invertebrates within the terrestrial exposure area. It is more likely that receptors are consuming a mixed diet from locations

within and outside the former FTA. In addition, the limited vegetation in the open terrestrial areas likely provide lower quality habitat (i.e., less attractive) than the surrounding forested areas outside the former FTA. Therefore, the focus of the risk characterization is on COPCs and receptors with HQs above 1 when the average EPC and the lowest-observed-adverse-effect level (LOAEL)-based toxicity reference value (TRV) are considered.

Selenium, Total PCBs, and endrin ketone are the only COPCs with HQs above 1 when the average EPC and LOAEL-based TRV are considered. These HQs range from 1.9 to 3.9 for the robin and from 2.3 to 2.9 for the shrew. The endrin ketone HQ for the shrew is below 1 when the average EPC and LOAEL-based TRV are considered. Based on the background evaluation, selenium is consistent with background and does not warrant further evaluation.

Given the relatively low levels of endrin ketone detected in the majority of the samples and uncertainties associated with the estimation of worm tissue concentrations in the food web model, it is expected that risks to wildlife due to endrin ketone are overestimated and not sufficient to warrant carrying endrin ketone further in the ERA process.

Although the robin and shrew HQs for Total PCBs are relatively low and there are some conservative assumptions included in the refined food web model, there may be a potential for risks to small insectivorous birds and mammals due to exposure to Total PCBs in surface soil and earthworms in the terrestrial portion of the former FTA. However, the refined food web model assumed a 100 percent earthworm diet for these receptors obtained only from within the terrestrial portion of the former FTA, when in reality this assumption is likely an overestimate and there may be low risk from the former FTA soils to these receptors.

6.2.2.3 Freshwater Benthic Invertebrates

The potential for risks to freshwater benthic invertebrates was evaluated by comparing sediment EPCs against benchmarks. Due to the small size of the freshwater sediment background data set, only a qualitative comparison against background conditions was conducted.

For benthic invertebrates, only one HQ above 1 was calculated in the Tier 2, Step 3a evaluation. The maximum EPC for Total PCB slightly exceeded the effect-based screening ecological value (SEV) resulting in an HQ of 1.3. No other COPCs exceeded the refined benchmarks in the Tier 2, Step 3a evaluation. Given the low magnitude of the HQs and the lack of other COPCs with HQs above 1, these results indicate that risks to benthic invertebrates are expected to be minimal within the wetlands of the former FTA and no further evaluation is warranted.

6.2.2.4 Aquatic Community

The potential for risks to freshwater aquatic invertebrates was evaluated by comparing surface water EPCs against benchmarks. Due to the small size of the freshwater surface water data sets, only a qualitative comparison against background conditions was conducted.

For aquatic invertebrates, total recoverable phase aluminum results in HQs above 1 in the Tier 2, Step 3a risk evaluation using the refined maximum EPC. When the average EPC is considered, all HQs are less than 1. None of the dissolved phase metals exceeded the refined SEVs and metals concentrations in most samples were similar to levels in background samples. The former FTA wetlands do not support a fish community so the surface water benchmarks may be overly conservative for the aquatic community present in the wetland and no further evaluation is warranted.

6.2.2.5 Wildlife in Freshwater Exposure Areas

The food web models identified HQs above 1 for the wetland, but not for the raccoon. The model for the wren may overestimate potential risks because it assumes that, when the wren is present, it only forages for benthic invertebrates within the wetlands of the former FTA. It is unlikely that the former FTA can support a population of wrens and it is more likely that any wrens present in the former FTA wetlands also forage from locations across, and potentially off, the peninsula. Therefore, the focus of the risk characterization is on COPCs and receptors with HQs above 1 when the average EPC and the LOAEL-based TRV are considered.

None of the COPCs had HQs above 1 when the average EPC and the LOAEL-based TRV were considered. Therefore, it can be concluded that risks to birds and mammals are expected to be minimal within the wetlands of the former FTA and no further evaluation is warranted.

6.2.3 Uncertainties in the ERA

As described in more detail in Sections 3.2.3 and 4.5 of **Appendix E**, there are several potential sources of uncertainty in the ERA. In general, the assumptions made at multiple points in the SRA tend to err on the side of overestimating risks. The more realistic exposure assumptions made in the Tier 2, Step 3a wildlife evaluation (e.g., use of UCLs and average EPCs) help to refine some of these uncertainties; however, other conservative assumptions remain (e.g., 100 percent earthworm diet from the former FTA).

The media-specific benchmarks represent one source of uncertainty because they are typically based on laboratory studies conducted under conditions likely to increase bioavailability (e.g., low total organic carbon [TOC] soils, bioavailable forms of the tested chemical) relative to what would likely be found under field conditions (e.g., higher TOC, weathered chemicals). Therefore, the benchmarks may overestimate risks.

Worm and soil concentrations from Site 4 on the VLF Peninsula were used to derive regression equations to predict worm tissue concentrations when site-specific worm tissue data were not available. However, there are some uncertainties for these regression equations including lack of true co-location in time and space between soil and worm tissue samples and the fact that the regression data set does not capture the full range of soil concentrations across the peninsula. It is also uncertain whether the soil-to-worm relationships at the former FTA are consistent with those associated with the VLF Peninsula towers.

There is the potential for the Total PAH and Total PCB concentrations used in the ERA to underestimate risks because they are based on the sum of only the individual detected PAHs or PCBs within a sample (i.e., assuming non-detects equal zero). An alternate calculation was also considered for the Tier 2, Step 3a evaluation which assumed non-detects were equal to the reporting limit. Overall, the results of the comparisons of PCB and PAH total calculations indicate that, while assuming non-detects are equal to the reporting limit (i.e., a more conservative assumption than used in the ERA) increases the EPCs, it does not change the overall findings of the ERA.

6.2.4 Conclusions of the ERA

The Tier 1 ecological SRA concluded that metals, PCBs, pesticides, SVOCs, and VOCs associated with surface soil, surface water, or freshwater sediment at the former FTA may pose potential risk to plants, invertebrates, and/or wildlife. Based on the results of the Tier 1 ecological SRA, a preliminary Tier 2, Step 3a BERA has been prepared to further assess the potential for adverse effects to ecological receptors at the former FTA. The Tier 2, Step 3a risk evaluation for the former FTA evaluated COPCs that failed the Tier 1 ecological SRA and the results are summarized as follows.

For terrestrial plants and soil invertebrates, HQs are greater than 1 for several metals and organic COPCs. Two metal COPCs with HQs above 1 are consistent with background (selenium, vanadium) and do not require further valuation and three of the organic COPCs are eliminated from further evaluation based on low frequency of detections (endrin aldehyde, carbazole, and dibenzofuran). For the remaining COPCs, there are significant uncertainties about the true bioavailability and toxicity of these COPCs to plants and invertebrates.

Based on a review of the benchmark sources and additional toxicity information and given the relatively low magnitude of the exceedances, the infrequency of the exceedances, it is expected that risks to plants and soil invertebrates are overestimated and not sufficient to warrant carrying these COPCs further in the ERA process.

For small insectivorous birds and mammals exposed to surface soil and earthworms, selenium, Total PCBs, and endrin ketone are the only COPCs with HQs above 1 when the average EPC and

LOAEL-based TRV are considered. As stated previously, selenium is consistent with background and the endrin ketone HQs are expected to overestimate risk due to the limited nature of the elevated concentrations and the uncertainties associated with the worm tissue estimates; therefore, these COPCs do not warrant further evaluation. Although the robin and shrew HQs are relatively low and there are some conservative assumptions included in the food web model, there may be a potential for risks to small insectivorous birds and mammals due to exposure to Total PCBs in surface soil and due to consumption of earthworms with bioaccumulated PCBs from the terrestrial portion of the former FTA. However, as stated previously, the refined food web model assumption of a 100 percent earthworm diet from the former FTA for these receptors likely overestimates risks and in reality, there may be low risk from the former FTA soils to these receptors.

In the wetland exposure area, risks are expected to be minimal and generally similar to background; no further evaluation is warranted for the aquatic community or the benthic invertebrate community. Risks to birds and mammals are also expected to be minimal within the wetlands of the former FTA and no further evaluation is warranted.

7.0 CONCEPTUAL SITE MODEL

As indicated in **Section 6.0**, the HHRA results identified the following risk drivers for one or more receptors/exposure areas:

- Surface Soil
  - *Soil Exposure Area 1:* Manganese
  - *Soil Exposure Area 2:* Manganese, benzo(a)pyrene, and Total PCBs
- Subsurface Soil
  - *Soil Exposure Area 1:* Manganese
  - *Soil Exposure Area 2:* Arsenic, manganese, and Total PCBs
- Groundwater (hypothetical future drinking water scenario)
  - Arsenic
  - Manganese
  - Trichloroethene
  - Vinyl chloride

The ERA results indicated there may be a potential risk to small insectivorous birds and mammals due to exposure to Total PCBs in surface soil and earthworms in the terrestrial portion of the former FTA.

As discussed in **Sections 4.0** and **5.0**, several metals were detected above PSLs in soil, sediment, surface water and groundwater. Metals are ubiquitous and occur naturally in soil as well as groundwater, sediment and surface water. In soil, the frequency of detection was relatively high for various metals above human health PSLs, including arsenic and manganese. Arsenic was found to have concentrations in site media less than or consistent with concentrations in site background. In sediment, arsenic exceeded the human health PSL. In surface water, arsenic and manganese exceeded the human health PSLs. In groundwater, arsenic was detected above the PSL at a maximum concentration of 16 µg/L in MW-5 in September 2015 and the maximum concentration of manganese was in MW-9 at 3,850 µg/L in September 2015.

There are no reported uses of chromium or other metals at the FTA in a manufacturing process or primary waste storage or disposal. The FTA is an abandoned gravel pit that was historically used for fire-training exercises from the 1960s through the 1980s and disposal of waste fuel oil and drum disposal. Buried drums were removed from the site and residual PCB contamination was identified. From 1999 to 2013, approximately 1.8 million gallons of water were pumped and treated and approximately 40,326 tons of soil have been removed from the FTA during the historical removal actions at the site. These actions would have also resulted in a reduction of site metals

concentrations at the site. Based on the data that show the remaining site soil metals concentrations are similar to site background levels, no release of metals to site media (including soil, groundwater, sediment and surface water) due to site activities is indicated and remediation of metals is not warranted.

PAHs are anthropogenic compounds that are found in man-made sources and are persistent in the environment. PAHs also occur naturally. PAHs are present in oil, coal, and tar deposits and in asphalt pavement. They are also found in terrestrial and aquatic plants, in soils and bottom sediments, in fresh and marine waters, and in natural deposits of peat as well as emissions from forest fires. Their presence at the FTA in soils is consistent with their slow environmental degradation and the presence of peat deposits at the site. The highest concentrations of PAHs were identified in surface soil at location FTA-SB-216. Benzo(a)pyrene was detected at a concentration of 4.3 mg/kg at this location. While other samples showed PAH concentrations above human health PSLs, concentrations were much lower, with the next highest benzo(a)pyrene concentration detected at 0.12 mg/kg at location FTA-SB-209. Therefore, it appears that the elevated PAH concentrations in surface soil at location FTA-SB-216, which is located on the western edge of the wetland, are localized and not widespread in soils across the site. In groundwater, PAHs were detected above human health PSLs infrequently. Additionally, their maximum detection in wells MW-5 and MW-10, which are located in the vicinity of the site near the subsurface peat deposits, indicates the peat may be acting as a natural source of the PAHs. In surface water, PAH exceedances of PSLs are relegated to location FTA-SW-06; therefore, the detected PAH concentrations in surface water are localized and not widespread across the site.

Figure 7-1 presents a CSM of Site 1 FTA as a cross-section parallel to the flow of groundwater extending from well MW-208 to downgradient wells MW-11 and MW-14. The CSM is based on the data from the lithological subsurface and analytical data collected during the previous investigations. The CSM illustrates the hydrogeology of the site and distribution of contaminants that are not ubiquitous substances and occur naturally in the environment (i.e., PCBs in soil and VOCs in groundwater).

At the former FTA, the source of the contaminants includes fire-training activities and disposal of waste fuel oil and buried drums. Therefore, the immediate exposure medium is the surface soil and subsurface soil. Based on the RI data evaluation and the HHRA, the soil contaminants at the former FTA above the human health PSLs can generally be grouped into two distinct soil exposure areas, referred to as Soil Exposure Area 1 and Soil Exposure Area 2. In general, Soil Exposure Area 1 contains lower chemical concentrations, and represents all the soil outside of Soil Exposure Area 2 (5.56 acres), and Soil Exposure Area 2 (1.45 acres) contains higher chemical concentrations. These areas are conceptually illustrated on **Figure 7-1**.

There is no evidence for current active sources releasing contaminants to the site media. The FTA was located within an abandoned gravel pit that was historically used for fire-training exercises. According to a 1988 preliminary assessment report, fire-training activities utilized two 4,200-gallon tanks, approximately 8 ft in diameter and 8 ft high in size, that had been cut in half. Waste fuel oil was burned in these tanks. The tanks were partially filled with water before the waste fuel oil was added and ignited. Some of the fuel oil is believed to have been released to the environment due to overfilling or overflow resulting from precipitation. Additionally, it was reported that waste No. 6 fuel oil was brought to the FTA and spread on the ground in the early 1980's when base Power Plant engines were switched from No. 6 fuel oil to No. 2 fuel oil. The DDA is a small area located on the southern portion of the FTA where buried drums and contaminated soil were identified in the late 2000's. **Figure 7-1** shows the approximate location of the two tanks used for fire-training exercises and the location of ground surface oil staining as observed during site walks conducted in the early 2000's. Previous removal actions have removed approximately 76 drums of waste oils and 10 drum carcasses, as well as the fire-training tanks and stained soil from the site.

Despite the previous removal actions, there is evidence for the following potential historical contamination sources that remain in place:

1. A potential residual source for PCB in soil is located within Soil Exposure Area 2 at the PCB Area 1/Anomaly 1 Drum Removal Area (illustrated on **Figure 7-1**) that was excavated by AGVIQ in 2013. PCB-contaminated soil was excavated to a depth of 2-ft. Confirmation soil samples were collected and PCB concentrations at three locations (PCBAREA1-013 [610 mg/kg], PCBAREA1-011 [240 mg/kg], PCBAREA1-014 [140 mg/kg]) on the western region of PCB Area 1/Anomaly 1 Drum Removal Area exceeded the PCB cleanup level of 100 mg/kg that was used by AGVIQ during the field effort. Further excavation was discontinued and the PCB-contaminated soil was left in place.
2. Groundwater samples obtained from MW-206, which is also in the vicinity of the firefighting area, exhibited the following VOC results in September 2015: TCE (10 µg/L); vinyl chloride (0.056 µg/L); and cis-DCE (22 µg/L). Well MW-206 has exhibited consistent concentrations of these three chemicals since 2012. Sources of the VOCs are potentially flammable solvents that were spilled or applied to the ground surface during firefighting training activities or from contents within the buried drums. It is likely the firefighting activities in the vicinity of this well, which is approximately 100 ft away from the tanks, impacted the subsurface, or flammable solvents could have reached this area during tank overfilling or overflow. Groundwater samples obtained from downgradient monitoring wells have shown low levels of VOCs, including a maximum vinyl chloride concentration of 0.84 µg/L at MW-9. VOCs would have impacted downgradient areas by migrating downward through the soil matrix to the

groundwater and then migrating in conjunction with the movement of groundwater in response to an external driving force such as gravity or hydrostatic pressure.

The CSM shows the following:

- The patterns of the detected VOCs in groundwater are parallel to the groundwater flow direction derived from the groundwater contour maps. This indicates these chemicals are following the predominant groundwater flow path towards the northeast.
- The absence of TCE and cis-DCE in monitoring wells downgradient of the potential source area suggests sufficient biodegradation of the TCE is occurring, as it moves downgradient from the potential source, to result in trace levels of the TCE biodegradation daughter product, vinyl chloride, in the downgradient portions of the site. This is supported by the negative oxidation reduction potential values measured in the field during the September 2015 groundwater sampling event (see Attachment B of **Appendix F**, the August 2017 Technical Memorandum Evaluation of Groundwater Analytical Results). Negative oxidation reduction potential values indicate anaerobic conditions in the subsurface, which are optimum conditions for biodegradation of chlorinated volatile compounds.
- The patterns of the detected PCBs in surface soil and subsurface soil suggest the source of the PCBs is the vicinity of the former fire-training activities as well as the drum burial area. The remaining impacted area that was left behind after the 2013 AGVIQ excavation represents an area of unacceptable risk. The extent of this area is approximately 300 square ft and located in the southwest portion of the site.

8.0 SUMMARY AND CONCLUSIONS

Section 8.0 presents the summary and conclusions of this RI.

8.1 Summary

Resolution Consultants has prepared this RI report on behalf of the Navy under the Comprehensive Long-Term Environmental Action Navy contract number N62470-11-D-8013. The primary objectives of this RI report are to determine the nature and extent of COCs and potential threat to human health and the environment, and provide a basis for determining whether or what types of response actions are required.

Site 1, FTA, occupies an area of 10.27 acres, of which 3.26 acres are wetland, located in the northern portion of the Cutler Peninsula. The FTA is located within an abandoned gravel pit that was historically used for fire-training exercises by NCTAMS LANT Det Cutler personnel from the 1960s to the 1980s. Fire-training activities utilized two 4,200-gallon tanks, approximately 8 ft in diameter and 8 ft high in size, that had been cut in half. Waste fuel oil was burned in these tanks. The tanks were partially filled with water before the waste fuel oil was added and ignited. Some of the fuel oil is believed to have been released to the environment due to overfilling or overflow resulting from precipitation. According to NCTAMS Fire Department officials, a maximum of 300–400 gallons of waste fuel were burned each year (HMM 1994). Additionally, it was reported that waste No. 6 fuel oil was brought to the FTA and spread on the ground in the early 1980's when base Power Plant engines were switched from No. 6 fuel oil to No. 2 fuel oil.

The DDA was originally identified as AOC 31 in the 2007 PSA Report due to the discovery of a drum in 2006. In 2010, the DDA was elevated from an AOC to an IR Site. The DDA was combined with the FTA in early 2012 due to their close proximity and similar contaminants, and both sites are referred to together as Site 1 (FTA).

Several historical investigations and removal actions have been performed to address contamination at the FTA. Groundwater, surface soil, subsurface soil, sediment, and surface water samples have been collected at the FTA at various times between 1991 and 2016. Resolution reviewed all available data and determined the appropriate and representative data to include in this RI. Based on the past activities, samples collected at the FTA have been analyzed for a variety of constituents. Soil samples have been analyzed for VOCs, SVOCs, PCBs, pesticides, and DRO/GRO and metals. Groundwater samples have been analyzed for VOCs, SVOCs, PCBs, PFASs, VPH, EPH, and metals. Surface water and sediment samples have been analyzed for VOCs, SVOCs, VPH, EPH, and metals. In addition, sediment samples have been analyzed for PCBs and pesticides.

From 1999 to 2013, approximately 1.8 million gallons of water were pumped and treated and approximately 40,326 tons of soil have been removed from the FTA during the historical removal actions at the site.

8.1.1 Nature and Extent of Contamination

Section 8.1.1 discusses the nature and extent of contamination at Site 1, FTA.

8.1.1.1 Soil

Based on the frequency of detection and exceedances of PSLs, and based on Resolution's evaluation of the data, the primary chemicals of interest in soil are PCBs (primarily PCB Aroclor-1260).

PCB Aroclor-1260 had the highest frequency of detection of the PCB Aroclors. PCB Aroclor-1260 was detected in 103 of 107 surface soil samples and 64 of 114 subsurface soil samples. PCB-contaminated soil was excavated in 2013 from two areas (PCB Area 1 and PCB Area 2) to a depth of 2 ft. PCB concentrations at three confirmation sample locations (PCBAREA1-013 [610 mg/kg], PCBAREA1-011 [240 mg/kg], PCBAREA1-014 [140 mg/kg]) exceeded the project-specific PCB removal action goal of 100 mg/kg.

While select PAHs were detected above PSLs, it appears that the elevated PAH concentrations in surface soil at location FTA-SB-216, which is situated on the western edge of the wetland, are localized and not widespread in soils across the site.

8.1.1.2 Sediment

In 2012, sediment samples were collected from eight locations (FTA-SED-01 through FTA-SED-08). In 2014, sediment samples were collected from the same eight locations. Samples in 2012 and 2014 were analyzed for: Total PCBs, metals, pesticides, TPH, VOCs, and SVOCs. One sediment sample was collected from location FTA-SED-07 in November 2016 and was analyzed for total and hexavalent chromium. The sediment samples were collected from the wetlands portion of the FTA.

Based on the frequency of detection and exceedances of PSLs, and based on Resolution's evaluation of the data, the primary chemical of interest in wetland sediment is PCB Aroclor-1260. PCB Aroclor-1260 was detected in 15 of 16 sediment sampling locations with a maximum concentration of 2.1 mg/kg from FTA-SED-04.

Select PAHs were detected above PSLs from location FTA-SED-01.

8.1.1.3 Surface Water

The primary chemical of interest in surface water is PCB Aroclor-1254. PCB Aroclor-1254 was detected at one surface water sampling location (FTA-SW-06) in 2014 at a concentration of 0.38 µg/L.

8.1.1.4 Groundwater

Based on September 2015 water level data from 26 site monitoring wells, the depth to groundwater ranges from less than 0.5 ft to approximately 13 ft bgs. Based on September 2015 monitoring well gauging data, the direction of shallow groundwater flow, in the surficial materials, is generally to the north. Hydrographs of groundwater elevation data reveal no discernible trends in seasonal groundwater flow patterns.

Based on the frequency of detection and exceedances of PSLs and based on Resolution's evaluation of the data, the primary chemicals of interest in groundwater are PFOS, PFOA, and chlorinated VOCs (cis-DCE, TCE, and vinyl chloride). Groundwater samples collected from site monitoring wells indicated maximum concentrations of PFOS and PFOA were detected above the PSLs in the northern portion of the site in MW-11 (0.25 µg/L of PFOS) and MW-14 (0.45 µg/L of PFOA). Groundwater samples obtained from MW-206 exhibited the following VOC results in September 2015: TCE (10 µg/L); vinyl chloride (0.056 µg/L); and cis-DCE (22 µg/L). MW-206 has exhibited consistent concentrations of these three chemicals since 2012. Groundwater samples obtained from downgradient monitoring wells have shown low levels of VOCs, including a maximum vinyl chloride concentration of 0.84 µg/L at MW-9.

8.1.2 Fate and Transport

As discussed in **Section 4.0**, Total PCBs (primarily PCB Aroclor-1260), PAHs, and metals in soil; PCB Aroclor-1260, benzo(a)pyrene, arsenic and total chromium in sediment; arsenic, manganese, thallium, PCB Aroclor-1254, and PAHs in surface water; and PFOS, PFOA, arsenic, hexavalent chromium, manganese, PAHs and chlorinated VOCs (cis-DCE, TCE, and vinyl chloride) in groundwater were identified above PSLs in the environment. The physical and chemical properties and potential release mechanisms and routes of migration for each of these constituent groups are discussed as follows.

8.1.2.1 PCBs

PCBs were detected above PSLs in soils, sediment, and surface water at the former FTA. Wastes gathered at the FTA and DDA have included electrical equipment and drums of waste oils and fluids, which are known to contain PCBs. The PCBs contained within the gathered wastes at the former FTA likely migrated via direct release to the ground surface and via leaking drum burial, followed by infiltration of the contamination into the soil. Sediment and surface water were likely impacted by storm water runoff and erosion of the contaminated soil at the surface and transport into the wetlands.

PCB Aroclors are composed of various combinations of PCBs with different properties such as vapor pressure, solubility, and viscosity. Data for PCBs were primarily available based on PCB Aroclor analysis with a smaller set of samples submitted for analysis of PCB homologues. PCB Aroclor-1260

had the highest frequency of detection of the PCB Aroclors. PCB Aroclor-1260 was detected in 103 of 107 surface soil samples and 64 of 114 subsurface soil samples. PCB Aroclor-1260 was detected in 15 of 16 sediment sampling locations. Total PCBs (as homologues) were detected in one surface water sampling location, and the concentration exceeded the human health-based USEPA NRWQC and MEDEP surface water criteria.

8.1.2.2 VOCs

VOCs at the former FTA are possibly the result of the use of combustible chlorinated solvents during fire-training activities and were possibly contained within buried drums. The VOC-containing solvents would have been spilled onto the ground surface and then infiltrated into the soil and into groundwater. The VOC detection pattern at the FTA is consistent with the characteristic environmental behavior of chlorinated solvents. Commonly, chlorinated solvents, when released to the environment (e.g., surface spills, historic disposal practices), will migrate downward through the soil matrix to the groundwater under density-driven flow, provided that the contaminant mass is sufficient to overcome pore throat entry pressure and the retardation properties of the soil matrix.

Chlorinated VOCs are generally mobile in the environment, primarily due to their high volatility, low adsorption to some soils, and low to high aqueous solubilities. They are relatively persistent in the environment because they do not degrade very easily under oxidizing conditions and therefore are not easily degraded by bacteria or taken up by other organisms in these environments. Chlorinated aliphatics, such as cis-DCE, TCE, and vinyl chloride, have been observed in groundwater at the former FTA. These hydrocarbons have variable solubilities and may be carried for some distance in groundwater. Because of these characteristics, the primary fate and transport mechanisms affecting VOCs are volatilization into the air and migration in groundwater. The high volatility of VOCs somewhat limits the extent to which surface water or groundwater transport will be a major transport process, because VOCs may volatilize out of unconfined or partially confined aquifers. Due to the high mobility of VOCs, a decrease in their concentrations is anticipated with time, as long as there is no additional input of these compounds.

Chlorinated VOCs also tend to undergo degradation reactions in anaerobic soil systems (reducing environments). The degradation reactions involve the progressive loss of chlorine ions from the molecular structure, resulting in a stepwise dechlorination under reducing conditions. An oxidizing environment would not favor large-scale reductive degradation of the TCE/cis-DCE/vinyl chloride series of compounds. However, some of the elevated metals data suggest the groundwater flow system is more reducing in some areas of the FTA.

8.1.3 Risk Assessment

Section 8.1.3 summarizes the risk assessment results.

8.1.3.1 HHRA

A summary of the HHRA conclusions is presented as follows by receptor; only COCs (i.e., risk drivers not attributable to background) are discussed. An overall summary of potential ELCR and HI results for the receptors evaluated at the FTA is presented in the HHRA (**Appendix D**, Tables 11.1.RME/CTE through 11.5.RME/CTE).

Current/Future Construction Worker: All total ELCRs for the RME and CTE current/future construction worker are within USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Target organ HIs are greater than MEDEP's and/or USEPA and MEDEP's target HI of 1 within the following exposure areas and media based on the following COCs:

- Soil Exposure Area 1
  - *Surface Soil:* Manganese (RME and CTE)
  - *Subsurface Soil:* Manganese (RME and CTE)
- Soil Exposure Area 2
  - *Surface Soil:* Manganese (RME and CTE), Total PCBs (RME only)
  - *Subsurface Soil:* Manganese (RME and CTE)

Current/Future On-Site Recreational User/Trespasser: The total ELCRs for the RME and CTE current/future recreational user/trespasser are within USEPA's target ELCR range of 10^{-6} to 10^{-4}. Total ELCRs/HIs are above MEDEP's target ELCR of 10^{-5} and/or USEPA and MEDEP's target HI of 1 within the following exposure areas and media based on the following COCs:

- Soil Exposure Area 2
  - *Surface Soil:* Total PCBs (RME and CTE), and benzo(a)pyrene, (RME only)

Future Outdoor Industrial Worker: Total ELCRs/HIs are above MEDEP's target ELCR of 10^{-5} and/or USEPA and MEDEP's target HI of 1 within the following exposure areas and media based on the following COCs:

- Soil Exposure Area 2
  - *Surface Soil:* Total PCBs (RME only)

Future Indoor Industrial Worker: The total potential ELCRs for the RME and CTE future indoor industrial worker are below USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Total potential HIs are below USEPA/MEDEP's target HI of 1. Therefore, no risk drivers or COCs are identified for the future industrial indoor worker.

Hypothetical Future On-Site Resident: Total ELCRs are above MEDEP's target ELCR of 10^{-5} and/or above USEPA/MEDEP's target HI of 1 within the following exposure areas and media based on the following COCs:

- Soil Exposure Area 2
  - *Surface Soil:* Total PCBs (RME and CTE) and benzo(a)pyrene, (RME only)
  - *Subsurface Soil:* Total PCBs (RME and CTE) and arsenic (RME only)
- Groundwater
  - Trichloroethene, vinyl chloride, arsenic, and manganese (RME and CTE)

COC Summary: The HHRA concluded that COCs not attributable to background for one or more receptors included:

- Surface Soil
  - *Soil Exposure Area 1:* Manganese
  - *Soil Exposure Area 2:* Manganese, benzo(a)pyrene, and Total PCBs
- Subsurface Soil
  - *Soil Exposure Area 1:* Manganese
  - *Soil Exposure Area 2:* Arsenic, manganese, and Total PCBs
- Groundwater (hypothetical future drinking water scenario)
  - Arsenic
  - Manganese
  - Trichloroethene
  - Vinyl chloride

8.1.3.2 ERA

Based on the results of the Tier 1 ecological SRA, a Tier 2, Step 3a BERA was prepared to assess the potential for adverse effects to ecological receptors associated with the former FTA.

Tier 2, Step 3a reevaluated COPCs that were retained at the conclusion of the Tier 1 ecological SRA and identified and eliminated from further consideration those COPCs that were retained because of the use of very conservative exposure scenarios. Using more realistic Tier 2, Step 3a assumptions, the Tier 1 ecological SRA risk estimates were recalculated for the pathways and COPCs retained at the end of the Tier 1 ecological SRA.

The Tier 2, Step 3a risk evaluation for the FTA evaluated COPCs that failed the Tier 1 ecological SRA. The ERA concluded that there may be a potential for risks to small insectivorous birds and mammals (American robin and the short-tailed shrew) due to exposure to Total PCBs in surface soil and due to consumption of earthworms containing bioaccumulated PCBs from the former FTA. The ERA also concluded that no further evaluation is warranted for the following receptors:

- Terrestrial Plant Community
- Soil Invertebrate Community
- Freshwater Benthic Invertebrate Community
- Freshwater Aquatic Community
- Wildlife in Freshwater Exposure Areas
- Herbivorous Wildlife in Terrestrial Exposure Areas

8.2 Conclusions and Recommendations

Section 8.2 summarizes the findings and provides recommendations for next steps.

8.2.1 Conclusions

Based on investigations and risk analyses, the preparation of a Feasibility Study (FS) is recommended. The FS will develop, screen, and evaluate alternative remedial actions that will address potential risks, identified in this RI report, to human health and ecological risk to small insectivorous birds and mammals.

Based on the CSM presented in **Section 8.0**, the following unacceptable risks and areas will be addressed in the FS:

- The patterns of the detected PCBs in surface soil and subsurface soil suggest the source of the PCBs is the vicinity in which the former fire-training activities took place as well as the drum burial area. The remaining impacted area that was left behind after the 2013 AGVIQ excavation represents an area of unacceptable risk. The extent of this area is approximately 300 square ft and located in the southwest portion of the site. The FS will focus on remedial alternatives to address the unacceptable risk from PCBs in soil in this portion of the site.
- The absence of TCE and cis-DCE in monitoring wells downgradient of the potential source area suggests sufficient biodegradation of the TCE is occurring, as it moves downgradient from the potential source, to result in trace levels of its biodegradation daughter product, vinyl chloride, in the downgradient portions of the site. This is supported by the negative oxidation reduction potential values measured in the field during the September 2015

groundwater sampling event. The FS will focus on remedial alternatives to continue to monitor the VOCs in groundwater.

8.2.2 Recommended Remedial Action Objectives

FS development will include remedial action objectives (RAOs) which seek to protect human and ecological receptors at Site 1. RAOs will focus on site-specific COCs, exposure routes, receptors, and preliminary remediation goals.

TABLES

This page intentionally left blank.

Table 1-1:
Summary of Previous Investigations and Removal Actions

Date	Event	Description	Reference
FTA			
1991	Site Investigation	The geophysical survey indicated the presence of two anomalies. Anomaly A indicated presence of contrasting subsurface materials (potentially fill), while anomaly B coincided with the approximate location of an oil stain. Soil samples were collected from nine borings advanced to 10 ft below the water table. Monitoring wells were installed in seven of the nine borings and groundwater samples were analyzed for the same analyte list as the soil samples.	HMM 1994
1999	Direct-Push Installation/Sampling and Test Pit Excavation	In May 1999, 14 direct-push points were installed and groundwater samples were collected at each location. No soil samples were submitted for laboratory analysis. Each groundwater sample was analyzed for VOCs, SVOCs, GRO, and DRO. In addition, 32 test pits were excavated. The tests pits were generally 5 to 7 ft deep, with a few other test pits several ft deeper.	EA 2002
1999	Contaminated Soil Excavation	During October 1999, 4,700 tons of visually-identified impacted soils were excavated by Foster Wheeler as part of site restoration activities. The excavation was initiated at the center of the impacted soil and was expanded using visual and flame-ionization detector screening. Foster Wheeler excavated approximately 0.25 acres of soil to approximately 4 ft below ground surface to where groundwater was encountered.	Foster Wheeler 2001
2001	Remedial Investigation	In August 2001, 14 shallow well points were installed by direct-push drilling methods at the FTA to further characterize the site. At the direct-push locations, groundwater samples were collected and analyzed for VOCs, GRO, and DRO. An additional four surface soil samples were collected adjacent to the perimeter of the Foster Wheeler excavation and analyzed for dioxins. In October 2001, 12 monitoring wells were installed at locations based on the August 2001 direct-push groundwater sample data. At this time, six subsurface soil samples were also collected.	EA 2002
2002	Field Investigation	In May 2002, 25 direct-push soil borings were used to assess the nature and extent of the petroleum contamination surrounding the 1999 remedial excavation area and determine whether the FTA was a source of the vinyl chloride found in groundwater samples previously collected downgradient from the FTA.	EA 2003

Table 1-1:
Summary of Previous Investigations and Removal Actions

Date	Event	Description	Reference
2003	Field Investigation	In November 2003, 27 direct-push soil borings were installed and 59 soil samples collected for analyses; 11 shallow direct-push wells were installed; 3 intermediate-depth direct-push wells were installed; and 1 deep permanent monitoring well was installed.	EA 2004
2004	Wetland Excavation and Restoration	In 2004, Tetra Tech excavated approximately 4,332 tons of DRO-contaminated soils (classified non-hazardous waste) and miscellaneous debris from the area designated as the Sand Wedge Excavation Area. The area of the excavation was approximately 18,841 square ft. After the soil was removed, the wetland was restored by placing a layer of organic enriched soil and seeding with a wetland plant mix and planting native saplings and other plants.	Tetra Tech 2005
2006	Soil Removal and Thermal Treatment	Starting in August 2006, UNITEC conducted Part 1 of a NTCRA to remove impacted soil at the FTA with TPH concentrations greater than the 400 mg/kg. After the thermal treatment was initiated, it was determined that the ABP was not able to treat the soils to below the cleanup goal for the 2006 removal action nor was it able to achieve the air emission standards for VOCs. Excavation and treatment activities ceased until 2008 when UNITEC returned to the site and completed the excavation and landfilled the contaminated soil. During the NTCRA excavation activities, a buried drum was discovered to the south of the excavation area.	UNITEC 2009
2008	Soil Removal and Thermal Treatment	In July 2008, UNITEC excavated an additional 9,412 tons (approximately 7,240 CY) of TPH-contaminated soils and disposed of it with the previously stockpiled soil from the August 2006 NTCRA.	UNITEC 2009
2007	Drum Discovery Investigation	On October 27, 2007, one soil boring was advanced at a buried drum location at the FTA where stained soil was observed during 2006 excavation activities. The soil boring was advanced to a total depth of 15 ft bgs and completed as a monitoring well.	Tetra Tech 2009
2009	Soil Removal	In May 2009, Tetra Tech conducted Part 2 of a NTCRA at the former FTA site. This work involved additional soil removal at the southwestern portion of the site. Tetra Tech excavated approximately 10,364 tons of soil. An area in the central portion of the site was created as wetlands to supplement the wetland area to the north (designated in 2004 as the Sand Wedge Excavation Area) as well as to provide additional habitat for wildlife.	Tetra Tech 2009
DDA			

Table 1-1:
Summary of Previous Investigations and Removal Actions

Date	Event	Description	Reference
2007	Site Discovery	As described previously, debris and one drum were uncovered during the 2006 NTCRA. The buried drum was encountered outside of the Site 1 NTCRA soil removal area. A limited removal, referred to as the Eastern DDA Removal Action, was performed in the summer of 2006 during which one crushed drum and impacted soil adjacent to the drum, were excavated by hand and containerized into 55-gallon drums. In total, seven 55-gallon drums and three 85-gallon over-pack drums containing soil and the crushed drum were removed from the site.	Tetra Tech 2007
2007	Preliminary Site Assessment	The DDA was investigated as part of a 2007 PSA and recommendations included excavation and removal of buried drums present in the immediate vicinity of the existing drum removal area, removal of impacted soil, and collection and analysis of soil samples for VOCs and DRO to verify that all of the impacted soil is removed from the AOC.	Tetra Tech 2008
2007	Site Investigation	As recommended from the 2007 PSA, geophysical surveys were conducted at the DDA and test pits were excavated between 2007 and 2009. Two geophysical anomalies were identified during the geophysical surveys: one area, identified as the northern asphalt debris area, was an area to the northwest of the FTA excavation, and is not within the DDA boundary. The second anomaly, referred to as the Western DDA Anomaly, was located south of the FTA and east of the drum described previously that was discovered in 2006. On October 26, 2007, four soil borings were advanced to depths of 7 to 15 ft below ground surface in the vicinity of the 2006 eastern DDA removal.	Tetra Tech 2009
2009	Western DDA Drum Removal	In July–September 2009, Shaw conducted Part 3 of a NTCRA at the Western DDA Anomaly to remove remaining petroleum-impacted soils, drums, and debris resulting from the historical use of waste fuel oil to conduct fire-training activities. A total of 34 drums were excavated from the anomaly area. Upon completion of all removal activities, the site was restored by backfilling with appropriate fill and grading to act as a wetland/heath to match the surrounding terrain. All disturbed areas were subsequently seeded and planted to compliment the surrounding area. A total of 1.8 million gallons of water was treated by an on-site water treatment system.	Shaw 2012
2010	Removal Site Evaluation	In 2010, the DDA was elevated from an AOC to an IR Site by MEDEP. In an effort to delineate the extent of PCB-contaminated soils at the DDA, a soil investigation was implemented in August 2010.	Tetra Tech 2011

Table 1-1:
Summary of Previous Investigations and Removal Actions

Date	Event	Description	Reference
2011	PCB Soil Investigation	The July 2011 PCB field investigation used the same sampling grid from the 2010 investigation. The grid was extended beyond the 2010 area to cover areas that required further investigation as recommended by Tetra Tech and MEDEP.	Tetra Tech 2012a
2012	Test Pit Investigation	In May 2012, a geophysical survey of the DDA area was conducted using EM-31 and EM-61 instrumentation. Four anomalies were identified south of the FTA excavation. Six test pits were excavated in late August 2012 at the anomalies. Drums were identified in three test pit locations and a drum top in one excavation.	Tetra Tech 2012b
2012	Time Critical Removal Action	A Time Critical Removal Action was performed in November 2012 to remove the contents of the drum that was punctured during test pit activities in August 2012. Additional investigation activities in the DDA were completed in late 2012 to characterize contaminants in soil, groundwater, surface water and sediments.	Tetra Tech 2012c
Site 1 FTA			
2012	Supplemental Remedial Investigation	In late 2012, a Supplemental Remedial Investigation was conducted by Tetra Tech. The objectives were to assess the current concentrations in soil, groundwater, surface water and sediment in areas that surrounded the previous excavations. Because PCBs were found in the vicinity of the DDA, PCBs were added to the list of analytes.	Tetra Tech 2013
2014	Field Sampling Investigation	In June 2014, Tetra Tech conducted groundwater, surface and subsurface soil, surface water and sediment sampling.	Tetra Tech 2014
2013	Removal Action	The removal of 35 buried 55-gallon drums was performed in August and September 2013. The drum removal activities were performed at Anomaly 1, Anomaly 4 and Anomaly 2. Soil was excavated from PCB-contaminated soil from two areas (PCB Area 1 and PCB Area 2) to a depth of 2-ft. A total of 202 CY of excavated material were managed and disposed of off-site.	AGVIQ 2015

Notes:

ft - feet.

mg/kg - milligrams per kilogram.

PCB - Polychlorinated biphenyl.

PSL - Project specific screening level. USEPA Regional Screening Level (RSL) for residential soil based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2016).

SVOC - Semivolatile organic compound.

VOC - Volatile organic compound.

(a) The value for Aroclor 1254 was used.

(b) The value for cadmium in the diet was used.

(c) The value for trivalent chromium was used.

(d) The value for manganese non-diet was used.

(e) The value for mercuric chloride was used.

(f) The value for endosulfan was used.

(g) The value for endrin was used.

(h) The value for pyrene was used.

(i) The value for fluorene was used.

(j) The value for anthracene was used.

(k) The value for 1,4-dichlorobenzene was used.

Notes:

ft - feet.

mg/kg - milligrams per kilogram.

PCB - Polychlorinated biphenyl.

PSL - Project specific screening level. USEPA Regional Screening Level (RSL) for residential soil based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2016).

SVOC - Semivolatile organic compound.

TPH - Total petroleum hydrocarbon.

VOC - Volatile organic compound.

(a) The value for Aroclor-1254 was used.

(b) The value for cadmium in the diet was used.

(c) The value for trivalent chromium was used.

(d) The value for manganese non-diet was used.

(e) The value for mercuric chloride was used.

(f) The value for endosulfan was used.

(g) The value for endrin was used.

(h) The value for anthracene was used.

(i) The value for 1,4-dichlorobenzene was used.

(j) The value for m-xylene was used.

(k) The value for toluene was used.

Table 4-3

Notes:
CAS - Chemical Abstracts Service.
ft - feet.
PFASs = Poly- and Perfluoroalkyl Substances.
PFOS = Perfluorooctanesulfonic acid or Perfluorooctane sulfonate
PFOA = Perfluorooctanoic acid.
PSL - Project specific screening level. PSL is the lowest of the following:
(1) USEPA Maximum Contaminant Levels (MCLs) for drinking water. Accessed October 2016.
https://www.epa.gov/ground-water-and-drinking-water/table-regulated-drinking-water-contaminants.
(2) USEPA Regional Screening Level (RSL) for tapwater based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens. Values calculated for PFOA and PFOS using the USEPA RSL Calculator (5/16). Default RSL exposure assumptions were used unless noted otherwise. Target cancer risk of 1x10-6 and a target hazard quotient of 0.1 used to account for cumulative effects on the same target organ. RfD for PFOS and PFOA (2x10-5 mg/kg-day) published in the following documents in May 2016: "Drinking Water Health Advisory for Perfluorooctane Sulfonate (PFOS)" and "Drinking Water Health Advisory for Perfluorooctanoic Acid (PFOA)". [EPA 822-R-16-004] were used.
(3) USEPA Vapor Intrusion Screening Level (VISL) for groundwater based on a residential exposure scenario, a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (5/16).
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbons.
ug/L - microgram per liter.
VOC - Volatile organic compound.
(a) The value for cadmium in water was used.
(b) The value for trivalent chromium was used.
(c) The value for manganese non-diet was used.
(d) The value for anthracene was used.
(e) The value for cis-1,2-dichloroethene is uesd for 1,2-dichloroethene, total.

Toluene	5 / 14	0.35 - 5.1	FTA-SW-07	57	NRWQC	0

Notes:

PCB - Polychlorinated biphenyl.

PSL - Project specific screening level. Lowest of the following:

- USEPA National Recommended Water Quality Criteria for Priority Pollutants (NRWQC). Value for Human Health for the consumption of water and organisms.
- MEDEP Surface Water Quality Criteria for human health consumption of water and organisms. 2012.
- Risk-based screening levels for surface water calculated using the USEPA Regional Screening Level (RSL) Calculator (May 2016) for a recreator adult/child scenario, based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens,

SVOC - Semivolatile organic compound.

ug/L - microgram per liter.

VOC - Volatile organic compound.

(a) Value for cadmium in water.

(b) USEPA Action Level for lead in water. http://water.epa.gov/drink/contaminants/index.cfm.

Notes:
mg/kg - milligrams per kilogram.
PCB - Polychlorinated biphenyl.
PSL - Project specific screening level. Calculated using the USEPA Regional Screening Level (RSL) Calculator (May 2016) for a recreator adult/child scenario, based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens
SVOC - Semivolatile organic compound.
VOC - Volatile organic compound.
(a) The value for Aroclor 1254 was used.
(b) The value for cadmium in the diet was used.
(c) The value for trivalent chromium was used.
(d) The value for manganese non-diet was used.
(e) The value for mercuric chloride was used.
(f) The value for endosulfan was used.
(g) The value for endrin was used.
(h) The value for pyrene was used.
(i) The value for fluorene was used.
(j) The value for anthracene was used.
(k) The value for phenol was used for 3- and 4-methylphenol.
(l) The value for toluene was used for methylcyclohexane.

APPENDIX A

PREVIOUS INVESTIGATIONS AND HISTORICAL REFERENCE FIGURES

This page intentionally left blank.

1.0 FTA – 1991 Site Investigation (HMM 1994)

The Site 1 FTA was initially investigated in 1991 as part of a Site Inspection (SI), which included field radiation screening, a geophysical survey, soil borings, and the installation of four monitoring wells. The details of the SI results can be referenced in the 1994 SI Report (HMM 1994). A soil gas survey was initially proposed; however, it was determined that the groundwater table was too shallow to obtain accurate data.

The results of field radiation screening indicated radiation levels were generally comparable to background and below established action levels. The geophysical survey indicated the presence of two anomalies. Anomaly A indicated presence of contrasting subsurface materials (potentially fill), while anomaly B coincided with the approximate location of an oil stain.

Soil samples were collected from nine borings advanced to 10 feet (ft) below the water table. Based on field screening and visual inspection, select soil samples were analyzed for volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), pesticides, polychlorinated biphenyls (PCBs), target analyte list (TAL) metals and total petroleum hydrocarbons (TPH).

Monitoring wells were installed in seven of the nine borings and groundwater samples were analyzed for the same analyte list as the soil samples.

TPH was detected in soil samples at concentrations between 12 and 120,000 parts per million (ppm). Methylene chloride was detected at a concentration of 14 ppm in one soil sample (SB-2). However, methylene chloride was detected in the laboratory blank, and appears the analyte is not indigenous to the site. The soil sample taken at MW-3A contained ethylbenzene at 0.05 ppm and total xylenes at 0.24 ppm. MW-3A also had aluminum at a concentration of 13,600 ppm. The soil samples collected at MW-3A had concentrations of SVOCs as high as 85,000 ppm.

Groundwater samples were collected at four monitoring wells: MW-1, MW-2A, MW-3A and MW-4A. There were detectable concentrations of TPH found in MW-2A (4.8 ppm), MW-3A (110 ppm, duplicate sample from MW-3A) and MW-4A (1.1 ppm). Monitoring well MW-3A had detectable concentrations of VOCs of 64 ppm. There were no detectable concentrations of PCBs in any of the groundwater samples. There were concentrations found at MW-3A in groundwater for SVOCs at concentrations as high as 100 ppm for naphthalene. The 1991 soil boring and well locations are illustrated on **Figure A-1**.

2.0 FTA – 1999 Investigation: Direct-Push Installation/Sampling and Test Pit Excavation (EA 2002)

In May 1999, 14 direct-push points (DP-2, DP-4 through DP-16) were installed and groundwater samples were collected at each location. No soil samples were submitted for laboratory analysis.

Each groundwater sample was analyzed for VOCs, SVOCs, gasoline range organics (GRO) and diesel range organics (DRO).

The analytical results for all but six samples contained a middleweight petroleum distillate(s) that was severely weathered. The four exceptions (DP-5-49, DP-6-38, DP-12-32, DP-15-16, and DP-16-17) exhibited no evidence of petroleum contamination. Vinyl chloride was detected at a level above the established MCL of 2 µg/L at DP-7 (3 µg/L) at a depth of 6 ft. There were other VOC detections at each soil boring; however, the concentrations were below the applicable MCLs. Naphthalene was detected in samples DP-7, DP-10, DP-11 and DP-14 at a depth of 6 ft. No other SVOCs were detected at each sample location. The 1999 soil boring and well locations are illustrated on **Figure A-2**.

During EA Engineering, Science, and Technology, Inc.'s (EA) 1999 investigation, 32 test pits were excavated in addition to the direct-push point samples taken at the FTA. The tests pits were generally 5 to 7 ft deep, with a few other test pits several ft deeper. Soils were screened in the field for vapor headspace using a photoionization detector (PID). Screening results with the PID ranged from 0 to 435 ppm, with the highest detection from the southwest corner of the FTA. No samples were submitted for laboratory analysis. The 1999 test pit excavation areas are illustrated on **Figure A-3**.

3.0 FTA – 1999 Contaminated Soil Excavation (Foster Wheeler 2001)

During October 1999, 4,700 tons of visually-impacted soils were excavated by Foster Wheeler as part of site restoration activities. The excavation was initiated at the center of the visually-impacted soil and was expanded using visual and flame-ionization detector screening. The 1999 soil excavation area is illustrated on **Figure A-2**. Foster Wheeler excavated approximately 0.25 acres of soil to approximately 4 ft below the ground surface to where groundwater was encountered.

Twenty-six confirmatory soil samples, including 18 sidewall and eight bottom samples, were collected on the perimeter and bottom of the excavation area. The confirmatory samples were analyzed for VOCs, SVOCs, TPH-GRO, TPH-DRO, and lead. The analytical results indicate that residual petroleum-contaminated soils remain above MEDEP action levels. The results range from values between 1,110 to 25,000 ppm. There were no exceedances for VOCs, SVOCs, or metals.

4.0 FTA – 2001 Remedial Investigation (EA 2002)

In August 2001, 14 shallow well points (DP-17, DP-18, DP-20 through DP-24 and DP-26 through DP-32) were installed by direct-push drilling methods at the FTA to further characterize the site. No soil samples were sent to a lab for analysis. Within the direct-push samples, groundwater samples were collected from well points DP-28 through DP-32 and each groundwater sample was analyzed for VOCs, vinyl chloride, GRO and DRO. Notable results of the direct-push groundwater sampling include vinyl chloride detections from well points DP-28, DP-29, DP-30 and DP-32 at concentrations

ranging from 2 to 26 µg/L which equals or exceeds the established MCL limit of 2 µg/L. Additionally, three chlorinated VOCs, 1,1-dichlororethene, cis-1,2-dichloroethene and tetrachloroethene (PCE), were detected at well points DP-28, DP-29, DP-30, and DP-31 at concentrations ranging from 0.6 to 20 µg/L. However, the concentrations were below the established MCLs. No other VOCs were detected in the direct-push groundwater samples. GRO was detected only at DP-30, at a concentration of 93 ppm, above the MEDEP Stringent Cleanup Goal of 50 ppm. DRO was detected from well points DP-17 and DP-26 through DP-32 at concentrations ranging from 64 to 1,800 ppm, above the MEDEP Stringent Cleanup Goal of 50 ppm.

An additional four surface soil samples were collected adjacent to the perimeter of the Foster Wheeler excavation (SSS-1 through SSS-4) and analyzed for dioxins. Toxicity Equivalent (TEQ) values of the dioxin 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) for these four samples ranged from 1.07 nanograms per kilogram (ng/kg) at SSS-3 to 3.49 ng/kg at SSS-4. The TEQ was derived from assigning individual toxicity equivalency factors to the chlorinated dibenzodioxin and chlorinated dibenzofurans congeners. The dioxin 2,3,7,8-TCDD is assigned a toxicity equivalency factor of 1.0. All other congeners have lower toxicity equivalency factors ranging from 0.5 to 0.001 ng/kg.

In October 2001, 12 monitoring wells (MW-5 through MW-14, MW-16 and MW-17) were installed at the FTA. Each one of these monitoring well locations was based upon the analytical results of the August 2001 direct-push groundwater samples. The wells were installed hydraulically downgradient of the FTA, focusing on the areas of elevated groundwater contamination concentrations. The 12 monitoring wells were sampled and the groundwater was analyzed for VOCs including vinyl chloride, SVOCs, TAL metals, PCBs, GRO, and DRO. Vinyl chloride was detected in samples collected from monitoring wells MW-7, MW-8, MW-9, MW-10, and MW-14 at concentrations ranging from 0.2 to 2 ppm, above the established MCL. No other VOCs were detected within the samples. Three SVOCs were detected in samples collected at MW-6 and MW-7, ranging in concentrations from 8 to 41 µg/L. No other SVOCs were detected. GRO was detected in samples collected at MW-5, MW-6, MW-7 and MW-10 at concentrations ranging from 57 to 310 ppm whereas DRO were detected in samples collected from MW-5 through MW-14, and MW-17 ranging in concentrations from 62 to 2,600 ppm. Arsenic was detected at MW-6, MW-7 and MW-10 at concentrations ranging between 15 and 23.8 ppm. Aluminum was detected in MW-17 at a concentration of 6,600 ppm, 10 times higher than the next highest aluminum concentrations. No other TAL metals were detected in the monitoring well locations.

An additional six subsurface soil samples (BSS-01 through BSS-06) were collected at the FTA during the October 2001 sampling event. Soil samples BSS-01 through BSS-3 were collected from visibly oil-stained surface soils southwest of the Foster Wheeler excavation in 1999. The additional three soil samples (BSS-04 through BSS-06), were collected as background samples. The location of these soil samples are illustrated on **Figure A-2**.

Additionally, the five monitoring wells that were installed in 1994 were abandoned during the 2001 field investigation. These wells include MW-2, MW-2A, MW-3, MW-3A and MW-4A.

5.0 FTA – 2002 Field Investigation (EA 2003)

In May 2002, 25 direct-push soil borings were installed to assess the current conditions and the nature and extent of the petroleum contamination surrounding the 1999 remedial excavation area and if the FTA was serving as a source for the vinyl chloride detections in groundwater samples previously collected downgradient from the FTA. The total depth of each boring was between 7 and 9 ft below ground surface (bgs). A total of 13 of the 25 soil samples were submitted for VOC analysis. All 25 soil samples collected at FTA in May 2002 were analyzed for both GRO and DRO.

Two chlorinated VOCs (PCE and trichloroethene [TCE]) were detected in soil sample FTA-SS-18-3-5 at concentrations of 0.0009 to 0.22 ppm, respectively. GRO was detected in 17 of the 25 samples (and one duplicate) in concentrations exceeding the MEDEP Stringent Cleanup Goal of 5 ppm. The GRO concentrations ranged from 8.9 at FTA-SS-20-3-5 to 1,300 ppm at FTA-SS-18-3-5. DRO was detected in 22 of the 25 samples at concentrations exceeding the MEDEP Stringent Cleanup Goal of 10 ppm. The DRO concentrations ranged from 55 ppm at FTA-SS-20-3-5 to 21,000 ppm at FTA-SS-18-3-5. The location of these soil samples are illustrated on **Figure A-2**.

6.0 FTA – 2003 Field Investigation (EA 2004)

In November 2003, an additional field investigation was conducted at the FTA which included:

- Installation of 27 direct-push soil borings and the collection of 59 soil samples for analyses
- Installation and groundwater sampling of 11 shallow direct-push wells (DP-33 through DP-40 and DP-44 through DP-46)
- Installation of three intermediate-depth direct-push wells (DP-41 through DP-43)
- Installation of one deep permanent monitoring well (MW-18)

A total of 59 direct-push soil samples were analyzed for DRO/GRO. A subset of eight soil samples were selected from depths exhibiting visual staining and additionally analyzed for VOCs.

Direct-push monitoring wells were installed in the shallow groundwater table to further delineate the extent of the shallow groundwater contamination. The three intermediate depth (DP-41 through DP-43) direct-push monitoring wells were installed for assessment of GRO/DRO groundwater contamination at the clay interface observed at well MW-6. Additionally, one deep permanent monitoring well was installed to assess DRO/GRO contamination at that depth. A total of 29 groundwater samples were collected from the 14 newly installed direct-push wells, the 14 existing permanent wells and the newly installed deep monitoring well. Each well location was sampled for GRO/DRO and VOCs. Twelve samples of groundwater from the direct-push wells were

also analyzed for vinyl chloride. The locations of these soil samples, monitoring wells and previous activities are illustrated on **Figure A-2**.

Within the eight of the 59 soil samples analyzed for VOCs, vinyl chloride was not detected. Vinyl chloride was detected at 51 of the 59 soil samples. PCE was also detected at SS-30-3-5, SS-51-2-3 and SS-52-5-6 at concentrations below the screening criteria of MEDEP Remedial Action Guidelines.

GRO was detected at soil sample locations SS-26, SS-30 through SS-33, SS-36 through SS-38, SS-42, SS-45 through SS-47 and SS-49 through SS-52 at concentrations ranging from 6.8 ppm to 1,800 ppm. DRO was detected in soil samples collected from SS-26, SS-28, SS-30 through SS-39, SS-42 through SS-47, SS-51 and SS-52 at concentrations ranging from 11 ppm to 52,000 ppm.

Vinyl chloride was detected at six groundwater sample locations (DP-37, DP-38, DP-43, MW-4, MW-7, MW-9, and MW-10) at concentrations ranging from 0.3 to 3 µg/L, with the highest concentrations found at MW-4 and MW-9. Five chlorinated VOCs were detected, but were below the MEDEP Maximum Exposure Guidelines and Federal MCL screening criteria. TCE was detected at DP-37 at a concentration of 2 µg/L. Additionally, GRO was detected at 10 groundwater sample locations (DP-37, DP-41, DP-42, DP-43, DP-46, MW-5, MW-6, MW-7, MW-10, and MW-13) at concentrations ranging from 68 to 660 ppm. DRO was detected in groundwater samples collected from DP-33, DP-37 through DP-46, MW-1, MW-5 through MW-14 and MW-18 ranging in concentrations from 53 to 3,200 ppm.

7.0 FTA – 2004 Wetland Excavation and Restoration (Tetra Tech 2005)

In 2004, Tetra Tech was contracted by the Department of the Navy, Engineering Field Activity, Northeast to perform a remedial action at the FTA site, including excavation activities and wetland restoration. Based upon the previous Remedial Investigations and site history, hydrocarbon-impacted soils were deposited into the wetland adjacent to the FTA. Previous investigations performed by EA in 2002 and 2003 concluded that the area north of the former FTA was impacted by petroleum-contaminated soils. This area was designated as the Sand Wedge Excavation Area. The location of the Sand Wedge Excavation Area is illustrated on **Figure A-4**.

In August 2004, Tetra Tech performed a visual delineation of the horizontal and vertical limits of the fill to be removed from the Sand Wedge Excavation Area, by collecting 4-to-6-ft-long geoprobe cores. Each geoprobe core was analyzed for DRO and visually examined to determine the depth of the native material and other soil characteristics.

Tetra Tech excavated approximately 4,332 tons of DRO-contaminated soils (classified non-hazardous waste) and miscellaneous debris from the Sand Wedge Excavation Area. The area of the excavation was approximately 18,841 square ft in size. After the soil was removed, the wetland was

restored by placing a layer of organic enriched soil and seeding with a wetland plant mix and planting native saplings and other plants.

8.0 FTA – 2006 Soil Removal and Thermal Treatment (UNITEC 2009)

Starting in August 2006, Universe Technologies, Inc. (UNITEC) conducted Part 1 of a non-time critical removal action (NTCRA) to remove impacted soil at the FTA with TPH concentrations greater than the 400 milligrams per kilogram (mg/kg). The limits of the NTCRA excavation boundaries were initially flagged and marked based upon the Maine East Coordinate Grid line system. The areas to be excavated were then established and broken into four quadrants (Quadrants I through IV), beginning in the northwest corner and continuing in a clockwise direction. UNITEC conducted the NTCRA in Quadrants I and II. UNITEC excavated approximately 10,088 tons (7,760 cubic yards [CY]) of TPH impacted soils associated with the previous firefighting activities. The NTCRA was conducted it the central area of the FTA and the TPH contaminated soil was treated in an on-site thermal asphalt batch plant (ABP).

After the thermal treatment was initiated, it was determined that the ABP was not able to treat the soils to below the cleanup goal for the 2006 removal action nor was it able to achieve the air emission standards for VOCs. Excavation and treatment activities ceased until 2008 when UNITEC returned to the site and completed the excavation and landfilled the contaminated soil (**Section 11.0**). The location of the UNITEC excavation area is illustrated on **Figure A-4**.

During the NTCRA excavation activities, a buried drum was discovered to the south of the excavation area. The drum was removed in 2006, but subsequent investigations at the site including a geophysical study and test pitting identified additional surficial debris to the east of the excavation area and additional buried drums located south of the excavation area. This area was addressed separately as AOC 31, DDA until it was renamed as Site 5, DDA in 2006. In 2012, the DDA was re-incorporated back into the FTA and Site 5 was designated for no further action. Activities associated with the DDA are described in **Sections 14.0** through **21.0**.

9.0 FTA – 2008 Soil Removal and Thermal Treatment (UNITEC 2009)

As described previously, in 2006, the proposed ABP thermal treatment of the soil in 2006 was unsuccessful and the remediation approach was changed from thermal treatment with an ABP to off-site transport and disposal. In July 2008, UNITEC excavated an additional 9,412 tons (approximately 7,240 CY) of TPH-contaminated soils and disposed of both the previously stockpiled soil from the August 2006 NTCRA and the 2008 contaminated soils.

In accordance with the project work plan, excavated soils were segregated into 1,500 CY stockpiles for sampling/waste characterization for landfill acceptance. Ten (10) soil samples were collected for disposal characterization and analyzed for toxicity characteristic leaching procedure (TCLP) metals, TCLP VOCs and TCLP SVOCs. Based on the analytical results, the soils were characterized as

non-hazardous and disposed of at Juniper Ridge Landfill. The location of the UNITEC excavation area is illustrated on **Figure A-4**.

10.0 FTA – 2007 Tetra Tech Drum Discovery Investigation (Tetra Tech 2009)

On October 27, 2007, one soil boring was advanced at a buried drum location at the FTA where stained soil was observed during 2006 excavation activities. From this boring, one soil sample (A32-SO-SB01-0002) was collected and analyzed for the presence of VOCs, SVOCs, PCBs, TAL metals, DRO, and GRO. The soil sample was collected from within 2 ft of the ground surface after removal of the top four inches of soil. The soil boring was advanced to a total depth of 15 ft bgs and completed as a monitoring well. The monitoring well was subsequently sampled on June 19, 2008 for VOCs, SVOCs, polycyclic aromatic hydrocarbons (PAHs), TAL metals, DRO, and GRO.

In soil, project action levels (PALs) were not exceeded for VOCs, SVOCs, PCBs, and GRO. Aluminum, arsenic, chromium, cobalt, iron, manganese, thallium, and vanadium were detected at concentrations that exceeded soil PALs at that time. Additionally, DRO was detected at a concentration (48 mg/kg) above the soil MEDEP Stringent Criterion for DRO of 10 mg/kg.

The groundwater MEDEP Stringent Criterion of 50 µg/L for DRO was also exceeded in this monitoring well (57 µg/L). Total arsenic and manganese were detected at concentrations that exceeded groundwater PALs at that time. PALs were not exceeded for VOCs, SVOCs, PAHs, and GRO. The location of this soil boring is illustrated on **Figure A-5**.

11.0 FTA – 2009 Soil Removal (Tetra Tech 2009)

In May 2009, Tetra Tech conducted Part 2 of a NTCRA at the former FTA site. This work involved additional soil removal at the southwestern portion of the site and the berms separating previously excavated Quadrants I through IV (**Figure A-4**). Tetra Tech conducted this soil removal due to the previous contractor reaching their contractual limit of soil excavation volume. Tetra Tech excavated approximately 10,364 tons of soil. During the 2009 soil removal action at the FTA, an area in the central portion of the site was created as wetlands to supplement the wetland area to the north (known as the Sand Wedge Excavation Area) as well as to provide additional habitat for wildlife.

Five waste characterization samples were collected from the soil stockpile and were analyzed for TCLP VOCs, TCLP SVOCs, and TCLP metals. Based on the analytical results, the soils were characterized as non-hazardous and disposed of at Casella Pinetree Landfill, located in Hamden, Maine.

12.0 FTA – 2012 Supplemental Remedial Investigation (Tetra Tech 2013)

In late 2012, a Supplemental Remedial Investigation was conducted at the Former FTA by Tetra Tech. The objectives of this investigation were to assess the current concentrations in soil,

groundwater, surface water and sediment in areas that surrounded the previous excavations. Due to the PCBs found within the vicinity of the DDA, PCBs were added to the list of analytes to further delineate the extent of PCB contamination.

Soil borings were completed in late October to early November 2012 and five new groundwater monitoring wells (MW-203, MW-206, MW-208, MW-210 and MW-218), one stream gauge and one piezometer (P-4) were installed at the site. Five new and seven existing groundwater monitoring wells were developed and sampled. Eight additional surface water and sediment samples were collected from areas throughout the enhanced wetland.

A total of 26 soil borings were advanced using either direct-push technology or hand drilling techniques around the wetlands. The locations of these soil and groundwater samples are illustrated on **Figure A-6**.

Soil samples were analyzed for VOCs, SVOCs, PCBs pesticides, and metals. Groundwater samples were analyzed for VOCs, SVOCs, PCBs, PFCs (per- and polyfluoroalkyl substances [PFAS]), volatile petroleum hydrocarbons (VPH), extractable petroleum hydrocarbons (EPH), and metals. Surface water and sediment samples were analyzed for VOCs, SVOCs, VPH, EPH, and metals. In addition, sediment samples were also analyzed for PCBs and pesticides.

The analytical data were compared to the project screening levels (PSLs), which represented the lowest applicable human health and ecological-risk based screening levels.

The following analytes were detected at concentrations that exceed the PALs for this investigation:

- *Soil:* VOC (vinyl chloride), PAHs (benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, indeno[1,2,3-cd]pyrene, and pyrene), pesticides (as 4,4-dichlorodiphenyltrichloroethane [DDT], endrin ketone), PCBs (PCB Aroclor-1254 and 1260), and metals
- *Groundwater:* VOCs (cis-1,2-dichloroethene, TCE, vinyl chloride), SVOCs (1,1-biphenyl), metals, and PFAS. EPH was detected as C11-C22 aromatics
- *Surface Water:* PAH (indeno[1,2,3-cd]pyrene) and metals
- *Sediment:* VOCs (acetone), SVOCs (2,4,5-trichlorophenol, 2,4,6-trichlorophenol, 2,4-dinitrophenol, 2-methylnaphthalene, acenaphthene, anthracene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[g,h,i]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd)pyrene, naphthalene, pentachlorophenol, phenanthrene, and pyrene), pesticides (4,41-DDT,

4,4'-dichlorodiphenyldichloroethylene [DDE], 4,4'-dichlorodiphenyldichloroethane [DDD] and endrin ketone), PCBs (PCB Aroclor-1260) and metals

13.0 FTA – 2014 Field Sampling Investigation (Tetra Tech 2014)

In June 2014, Tetra Tech performed an investigation of the FTA, consisting of groundwater, surface and subsurface soil, surface water and sediment sampling. Soil samples were analyzed for VOCs, SVOCs, VPH, PCBs, pesticides, and metals. Groundwater samples were analyzed for VOCs, SVOCs, PCBs, perfluorooctanesulfonic acid (also known as perfluorooctane sulfonate) (PFOS)/perfluorooctanoic acid (PFOA), VPH, EPH, and metals. Surface water and sediment samples were analyzed for VOCs, SVOCs, TPH, PCBs, and metals. The locations of these soil and groundwater samples are illustrated on **Figure A-7**.

The following analytes were detected at concentrations that exceed the PALs for this investigation:

- *Soil:* PAHs (benzo(a)pyrene), pesticides (4,4-DDT, dieldrin, endrin aldehyde, endrin ketone and methylchlor epoxide), PCBs (as PCB Aroclor- 1260), and metals
- *Groundwater:* VOCs (cis-1,2-dichloroethene, TCE, vinyl chloride), SVOCs (as 1,1-biphenyl), total and dissolved metals, and PFOS and PFOA. TPH was detected as C11-C22 aromatics
- *Surface Water:* PAH as indeno(1,2,3-cd)pyrene and metals
- *Sediment:* VOCs (acetone), SVOCs (bis[2-ethyhexyl]Phthalate, chrysene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, phenanthrene, and pyrene), pesticides (4,41-DDT, 4,4'-DDE, 4,4'-DDD, endosulfan sulfate, endrin aldehyde, endrin ketone and dieldrin), PCBs (PCB Aroclor-1260), PAHs (2,4,6-trichlorophenol, 2,4-dinitrotoluene, acenaphthene, benzo(a)pyrene, benzo(a)anthracene, indeno[1,2,3-cd]pyrene and pentachlorophenol), and metals

14.0 DDA – Site Discovery (Tetra Tech 2007)

As described in **Section 7.0**, debris and one drum were uncovered during the 2006 NTCRA. The buried drum was encountered outside of the Site 1 NTCRA soil removal area. The drum and soils surrounding the drum were removed by Clean Harbor Environmental Services in 2006 and transported to their Rumery Road oil recovery facility in South Portland, Maine.

A sample of the material collected in 2006 from the drum contained DRO at a concentration of 46,000 mg/kg. VOCs, SVOCs, and PAHs were not detected in this sample. Metals were detected below hazardous levels according to TCLP results. The sample was not analyzed for the presence of PCBs (Tetra Tech 2007).

A limited removal, referred to as the Eastern DDA Removal Action, was performed in the summer of 2006 during which one crushed drum and impacted soil adjacent to the drum, were excavated by

hand and containerized into 55-gallon drums. In total, seven 55-gallon drums and three 85-gallon over-pack drums containing soil and the crushed drum were removed from the site and transported to the Clean Harbors Rumery Road oil recovery facility in South Portland, Maine.

15.0 DDA – 2007 Preliminary Site Assessment (Tetra Tech 2008)

The DDA was investigated as part of a 2007 PSA and recommendations included excavation and removal of buried drums present in the immediate vicinity of the existing drum removal area, removal of impacted soil, and collection and analysis of soil samples for VOCs and DRO to verify that all of the impacted soil is removed from the AOC. A surface geophysical survey was also recommended to identify subsurface anomalies that might indicate the presence of additional buried containers (Tetra Tech 2007).

16.0 DDA – 2007 Site Investigation (Tetra Tech 2009)

As recommended from the 2007 PSA, geophysical surveys were conducted at the DDA and test pits were excavated between 2007 and 2009. Two geophysical anomalies were identified during the geophysical surveys: one area, identified as the northern asphalt debris area, was an area to the northwest of the FTA excavation, and is not within the DDA boundary. The second anomaly, referred to as the Western DDA Anomaly, was located south of the FTA and east of the drum described above that was discovered in 2006. Due to site access and equipment limitations, only EM-31 was utilized to conduct surveys in the extreme southern portion of the survey area. It was suggested that the EM-31 methodology might have been impacted by interference from grounding wires located in the southwestern portion of the survey area and anomaly areas could not be investigated.

On October 26, 2007, four soil borings were advanced to depths of 7 to 15 ft bgs in the vicinity of the 2006 eastern DDA removal (**Figure A-8**). A total of eight soil samples (two from each boring) were collected from these soil borings, and all samples were analyzed for VOCs, SVOCs, DRO and GRO. Soil borings SB01 and SB03 were advanced until refusal (7 and 9.5 ft bgs, respectively), whereas SB02 and SB04 were advanced to 10 and 15 ft bgs, respectively. Each of these soil borings were utilized as a temporary monitoring well from which groundwater samples were collected. All groundwater samples were analyzed for VOCs, DRO, and GRO.

Soil: VOCs, SVOCs, and GRO were not detected above the MEDEP Stringent Criteria. The MEDEP Stringent Criteria for DRO (10 mg/kg) was exceeded in three of the eight soil samples, all of which were collected from the 0 to 2 ft depth.

Groundwater: PALs for groundwater were exceeded by only two VOCs (1,4-dichlorobenzene and TCE) and in all four samples analyzed for DRO. PALs for GRO were not exceeded.

17.0 DDA – 2009 Western DDA Drum Removal (Shaw 2012)

In July–September 2009, Shaw conducted Part 3 of a NTCRA at the Western DDA Anomaly to remove remaining petroleum-impacted soils, drums, and debris resulting from the historical use of waste fuel oil to conduct firefighting training activities. A total of 34 drums were excavated from the anomaly area. The approximate limits of the excavation are illustrated on **Figure A-8**.

Samples collected from the stockpiled, excavated soils, were analyzed for PCBs. PCBs were detected at concentrations of 91.4 mg/kg, which exceeded Toxic Substances Control Act (TSCA)-regulated levels (> 50 mg/kg), which triggered a requirement to dispose of the material as TSCA-regulated waste. Additionally, TPH DRO/GRO were analyzed at eight confirmation sample locations (bottom and sidewall composite samples) and the results shown that the site remedial goal of 400 ppm had been achieved and that no additional excavation was required to address petroleum. A total of 1,127 tons of petroleum contaminated soil were transported and disposed off-site as hazardous waste. Confirmation samples that were collected from the excavation indicated that the extent of DRO-contaminated soils had been delineated; however, elevated levels of PCBs remained in the site soils. Upon completion of all removal activities, the site was restored by backfilling with appropriate fill and grading to act as a wetland to match the surrounding terrain. All disturbed areas were subsequently seeded and planted to compliment the surrounding area.

At the time of Shaw's mobilization, the open excavation resulting from prior remedial activities at the site was completely filled with groundwater. The resulting pond covered approximately 1.8 acres and was up to 9 ft deep. Dewatering was performed to allow backfilling and restoration activities. Samples collected from the ponded water in the open excavation exhibited low levels of petroleum contamination. However, these concentrations were low enough to be compatible with remedial goals and therefore allow discharge within site boundaries. An on-site water treatment system was constructed to dewater the pond.

The water treatment system consisted of two parallel treatment trains which reduced turbidity and treated for petroleum contamination. The system had a total operating capacity of 500 gpm, but was normally operated at approximately 250 gpm. Treated water was discharged to a location south of the site. A total of 1.8 million gallons of water was treated by the system.

18.0 DDA – Removal Site Evaluation (Tetra Tech 2011)

In 2010, the DDA was elevated from an AOC to an Installation Restoration Site by MEDEP. In an effort to delineate the extent of PCB-contaminated soils at the DDA, a soil investigation was implemented in August 2010. A grid of soil borings was used to refine the horizontal and vertical extent of remaining soils with PCBs at concentrations exceeding 1.0 mg/kg. The sampling grid extended beyond the footprint of the 2009 excavation in the directions of highest detected contaminant levels. The previous excavation samples collected along the southern grid line were

below 1.0 mg/kg, therefore, soil sampling activities focused on the areas to the north, west, and east of the excavation area. A higher density of samples was planned along the western side of the grid pattern since the highest concentrations of PCBs were previously detected in the northwest quadrant of the former excavation. Sample density and sample depths were refined in the field based on real-time analysis of screening results to optimize the use of resources. Field screening utilized the Dexsil™ L-2000 method, which provided real-time screening PCB measurements.

This field effort included the advancement of 44 soil borings at both pre-selected and field-selected grid locations, field-screening of soil samples and laboratory analysis of a select group of samples for PCBs. Results obtained from the 2010 field investigation were reported in the Removal Site Evaluation (RSE) Report (Tetra Tech 2011a). The RSE recommended additional soil borings in the northwestern and southwestern quadrants to further assess the lateral extent of elevated PCBs in soil to the west and southwest. Furthermore, elevated field screening results from soil samples collected from the southeast area of the sampling grid did not correlate well with laboratory results, suggesting a potential source of chloride other than PCBs. Additional soil investigation was recommended in the southeast quadrant to further delineate the nature and extent of elevated screening levels measured in soil. No further assessment was recommended to delineate the extent of PCBs in soil in the northeast or southeast quadrants of the DDA (Tetra Tech 2011a). Soil boring locations are illustrated on **Figure A-8**.

In comments on the RSE (February 24, 2011), MEDEP requested additional assessment northeast of DDA-NE-6D and DDA-NE-5D. The Navy responded (June 10, 2011–Tetra Tech 2011b) and agreed to advance additional borings in the northeastern quadrant.

19.0 DDA – PCB Soil Investigation (Tetra Tech 2012a)

The July 2011 field investigation utilized the same sampling grid that had been used during the 2010 investigation, with the center of the grid located in the approximate center of the former drum removal area. The grid was extended beyond the 2010 area to cover areas that required further investigation as recommended by Tetra Tech (2011a) and MEDEP (2011). A total of 27 borings were pre-selected as step-out locations for the 2011 investigation, and 14 additional boring locations were selected during the field investigation based on the results of soil sample field screening data.

The highest concentration was detected in a southwest quadrant surface soil sample (0 to 2 ft bgs) from soil boring DDA-SW-3N (260 mg/kg). Concentrations of PCBs detected in off-site laboratory samples collected from remaining borings advanced in the southwest quadrant were below 1.0 mg/kg with the exception of the surface soil sample collected from DDA-SW-2I (1.11 mg/kg). The second highest PCB concentration was detected in the surface soil sample collected from soil boring DDA-NE-7D (68.1 mg/kg). PCB concentrations exceeding 1.0 mg/kg were detected in the

surface soil samples collected from soil boring DDA-NE-10D (7.4 and 10.6 mg/kg [blind duplicate]) located approximately 30 ft to the north of DDA-NE-7D, in the surface soil sample collected from soil boring DDA-NE-7I (2.24 mg/kg) located approximately 50 ft to the east of NE-7D, in the surface soil sample from DDA-NE-3E (2.67 mg/kg) and in the surface soil sample DDA-E-1E (3.45 mg/kg). Soil boring locations are illustrated on **Figure A-8**.

20.0 DDA – Test Pit Investigation (Tetra Tech 2012b)

In May 2012, a geophysical survey of the DDA area was conducted using EM-31 and EM-61 instrumentation after the area was cleared of vegetation. Four EM geophysical anomalies (Anomalies 1 through 4) were identified south of the FTA excavation. Six test pits were excavated in late August 2012 to assess the four geophysical anomalies discovered in May 2012. Drums were identified in three test pit locations (TP-1A and TP-1B, TP-2 and TP-4) and a drum top was identified in one excavation (TP- 3). **Figure A-8** presents the relation of the test pits and the anomalies. Details of the identified drums are as follows:

- Two drums were discovered in TP-1A; one drum was punctured during the excavation and contained an oily material. None of the contents were released to the environment, and PCBs were not detected in the sample collected from the crushed drum. A fingerprint analysis indicated that the drum contents were similar to motor oil. Plastic sheeting was placed inside the punctured drum and the drum was wrapped in plastic sheeting prior to being covered with the excavated soil and left in place until removal activities could occur as described hereafter.
- Two drums were discovered in TP-1B.
- Three drums were discovered in TP-2, and these drums were located beneath the previous excavation area conducted in November 2009.
- Two drums and one crushed drum were discovered in TP-4.

Identified drums were left in place and excavated soils were used to cover the drums prior to completing the investigation. In addition, five surface soil and two subsurface soil samples were collected from the test pits and two surface trenches. VOC and SVOC concentrations did not exceed PSLs in subsurface or surface soil samples with the exception of one surface soil sample (FTATP1BS- 0.501). Five oil-related parameters and SVOCs were detected above their respective PSLs in the surface soil sample collected from TP-1B. PCBs and metals exceeded their respective PSLs in surface soil samples collected from test pits TP-1A, TP-1B and the two trenches. PCBs and metals concentrations exceeded PSLs in subsurface soil samples collected from test pits TP-2 and TP-4. Concentrations of EPH exceeded PSLs in the subsurface soil samples collected from test pit TP-2. Pesticides exceeded their respective PSLs in each of the surface soil samples and one of the subsurface soil samples collected from test pit TP-2 (**Figure A-8**).

21.0 DDA – 2012 Time Critical Removal Action (Tetra Tech 2012c)

A Time Critical Removal Action was performed in November 2012 to remove the contents of the drum that was punctured during test pit activities in August 2012. Additional investigation activities in the DDA were completed in late 2012 to characterize contaminants in soil, groundwater, surface water and sediments emanating from the DDA (**Figure A-8**). This investigation included:

- *Soil borings:* Installation and sampling of soil borings in and around the DDA to evaluate the nature and extent of contaminants from the DDA. Samples were analyzed for VOCs, SVOCs, PCBs, pH, TAL metals and pesticides at several locations.
- *Groundwater:* Installation and sampling of monitoring wells and piezometer to evaluate migration of contaminants from the DDA to groundwater, and to evaluate groundwater elevations. Samples were analyzed for VOCs, VPH, EPH, SVOCs, total and dissolved metals and PCBs.
- *Surface Water/Sediment:* Samples collected in the enhanced wetland downgradient of the DDA to evaluate migration of contaminants from the DDA. Surface water samples were analyzed for VOCs, VPH/EPH, SVOCs and total and dissolved metals. Sediment samples were analyzed for VOCs, SVOC, PCBs, pesticides, total organic carbon, pH, metals and VPH/EPH.

22.0 FTA – 2013 Removal Action (AGVIQ 2015)

The objective of the removal action performed by AGVIQ was to remove the buried drums and associated soil from three areas and the removal of the PCB-contaminated soil from two areas within the former DDA portion of the FTA. The location of the AGVIQ removal activities is illustrated on **Figure A-9**.

The removal of 35 buried 55-gallon drums was performed in August and September 2013. The drum removal activities were performed at Anomalies 1, 2 and 4. During drum removal operations, efforts were made to keep intact drums whole and any liquids contained in the drum were removed and containerized in overpack containers. There were a total of 25 intact drums removed from Anomaly 1. During the excavation at Anomaly 1, an additional 10 drum carcasses were removed and placed in a roll-off container for offsite disposal as TSCA waste. Anomaly 2 contained 10 intact drums that were removed and one drum carcass that was placed in the roll-off container for disposal.

Intact drums were not found in Anomaly 4; however, four drum carcasses and scrap metal were excavated and placed in a roll-off container.

PCB-contaminated soil was excavated from two areas (PCB Area 1 and PCB Area 2) to a depth of 2 ft. Confirmation soil samples were collected to verify that the PCBs removal action goals were

met. The confirmation sampling began on September 18, 2013. The PCB concentrations were less than the 100 mg/kg cleanup level in PCB Area 2 and the eastern side of PCB Area 1. The PCB concentration was greater than the cleanup levels at six locations on the western region of PCB Area 1. One ft of soil was excavated from the areas where the PCB concentrations had exceeded the action level and then resampled for PCBs. A review of the soil sample analytical results showed that the PCB concentrations at three locations exceeded the PCB cleanup level. Due to funding limitations, further excavation was discontinued and the portion of the excavation containing PCBs greater than the cleanup level was marked with plastic sheeting. A cumulative total of 202 CY of excavated material were managed and disposed of as waste.

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing only the detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples without any detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".

VOCs	XYLENES, TOTAL CALC (b)	RA-1330-20-7	mg/kg	< 0.01 U									

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de limit within the sample is presented as a non-detect value. Calculated totals have a CAS r beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS r
beginning with "RA-".

VOCs	XYLENES, TOTAL CALC (b)	RA-1330-20-7	mg/kg									

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de limit within the sample is presented as a non-detect value. Calculated totals have a CAS n beginning with "RA-".

VOCs	XYLENES, TOTAL CALC (b)	RA-1330-20-7	mg/kg										

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS r
beginning with "RA-".

VOCs	TRICHLOROETHENE	79-01-6	mg/kg										
VOCs	TRICHLOROFLUOROMETHANE	75-69-4	mg/kg										
VOCs	VINYL CHLORIDE	75-01-4	mg/kg										
VOCs	XYLENES, TOTAL (a)	1330-20-7	mg/kg										
VOCs	XYLENES, TOTAL CALC (b)	RA-1330-20-7	mg/kg										

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS r
beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS r
beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples with detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting det limit within the sample is presented as a non-detect value. Calculated totals have a CAS r beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples with detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting det limit within the sample is presented as a non-detect value. Calculated totals have a CAS r beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples with detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting det limit within the sample is presented as a non-detect value. Calculated totals have a CAS r beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS r
beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de limit within the sample is presented as a non-detect value. Calculated totals have a CAS r beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples with detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de limit within the sample is presented as a non-detect value. Calculated totals have a CAS r beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples with detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting det limit within the sample is presented as a non-detect value. Calculated totals have a CAS r beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de limit within the sample is presented as a non-detect value. Calculated totals have a CAS r beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS
beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS
beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de limit within the sample is presented as a non-detect value. Calculated totals have a CAS r beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS r
beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS r
beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de limit within the sample is presented as a non-detect value. Calculated totals have a CAS r beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS
beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples with detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS
beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
EPH - Extractable Petroleum Hydrocarbons.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples wit
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting de
limit within the sample is presented as a non-detect value. Calculated totals have a CAS r
beginning with "RA-".

Notes:

< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
FD - Field duplicate.
ft - feet.
J - Estimated value.
N - Normal sample.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
ug/L - microgram per liter.
U - Not detected.
VOC - Volatile organic compound.
(a) Total concentrations for use in the risk assessment were calculated per sample by summing only the detected individual compounds (i.e., xylene) concentrations. For samples without any detections of individual compounds (i.e., xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".

Notes:

< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
F - Filtered sample.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
ug/L - microgram per liter.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing only the detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples without any detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".

Notes:

< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
F - Filtered sample.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
ug/L - microgram per liter.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing only the detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples without any detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
F - Filtered sample.
FD - Field duplicate.
ft - feet.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
ug/L - microgram per liter.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing only the detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples without any detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".

Notes:

< - Result not detected above laboratory reporting limit.

CAS - Chemical Abstracts Service.

F - Filtered sample.

FD - Field duplicate.

J - Estimated value.

HPAH - High molecular weight PAH.

LPAH - Low molecular weight PAH.

N - Normal sample.

PAH - Polycyclic Aromatic Hydrocarbon.

PCB - Polychlorinated Biphenyl.

SVOC - Semivolatile organic compound.

TPH - Total Petroleum Hydrocarbon.

ug/L - microgram per liter.

U - Not detected.

UJ - The analyte was not detected; and the reporting limit is approximate.

UR - Unreported/rejected.

VOC - Volatile organic compound.

VPH - Volatile Petroleum Hydrocarbons.

(a) Lab calculated value; only used when individual compound data not available.

(b) Total concentrations for use in the risk assessment were calculated per sample by summing only the detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples without any detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".

Notes:

< - Result not detected above laboratory reporting limit.

CAS - Chemical Abstracts Service.

F - Filtered sample.

FD - Field duplicate.

J - Estimated value.

HPAH - High molecular weight PAH.

LPAH - Low molecular weight PAH.

N - Normal sample.

PAH - Polycyclic Aromatic Hydrocarbon.

PCB - Polychlorinated Biphenyl.

SVOC - Semivolatile organic compound.

TPH - Total Petroleum Hydrocarbon.

ug/L - microgram per liter.

U - Not detected.

UJ - The analyte was not detected; and the reporting limit is approximate.

UR - Unreported/rejected.

VOC - Volatile organic compound.

VPH - Volatile Petroleum Hydrocarbons.

(a) Lab calculated value; only used when individual compound data not available.

(b) Total concentrations for use in the risk assessment were calculated per sample by summi
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples v
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting c
limit within the sample is presented as a non-detect value. Calculated totals have a CA
beginning with "RA-".

Notes:

< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
F - Filtered sample.
FD - Field duplicate.
J - Estimated value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
TPH - Total Petroleum Hydrocarbon.
ug/L - microgram per liter.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
VPH - Volatile Petroleum Hydrocarbons.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summi
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples w
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting c
limit within the sample is presented as a non-detect value. Calculated totals have a CAS
beginning with "RA-".

Notes:

< - Result not detected above laboratory reporting limit.

CAS - Chemical Abstracts Service.

FD - Field duplicate.

ft - feet.

J - Estimated value.

HPAH - High molecular weight PAH.

LPAH - Low molecular weight PAH.

mg/kg - milligram per kilogram.

N - Normal sample.

PAH - Polycyclic Aromatic Hydrocarbon.

PCB - Polychlorinated Biphenyl.

SVOC - Semivolatile organic compound.

TPH - Total Petroleum Hydrocarbon.

U - Not detected.

UJ - The analyte was not detected; and the reporting limit is approximate.

UR - Unreported/rejected.

VOC - Volatile organic compound.

VPH - Volatile Petroleum Hydrocarbons.

(a) Lab calculated value; only used when individual compound data not available.

(b) Total concentrations for use in the risk assessment were calculated per sample by summing only the detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples without any detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".

Notes:

< - Result not detected above laboratory reporting limit.

CAS - Chemical Abstracts Service.

FD - Field duplicate.

ft - feet.

J - Estimated value.

HPAH - High molecular weight PAH.

LPAH - Low molecular weight PAH.

mg/kg - milligram per kilogram.

N - Normal sample.

PAH - Polycyclic Aromatic Hydrocarbon.

PCB - Polychlorinated Biphenyl.

SVOC - Semivolatile organic compound.

TPH - Total Petroleum Hydrocarbon.

U - Not detected.

UJ - The analyte was not detected; and the reporting limit is approximate.

UR - Unreported/rejected.

VOC - Volatile organic compound.

VPH - Volatile Petroleum Hydrocarbons.

(a) Lab calculated value; only used when individual compound data not available.

(b) Total concentrations for use in the risk assessment were calculated per sample by summ
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples v
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting
limit within the sample is presented as a non-detect value. Calculated totals have a CA
beginning with "RA-".

Notes:

< - Result not detected above laboratory reporting limit.

CAS - Chemical Abstracts Service.

FD - Field duplicate.

ft - feet.

J - Estimated value.

HPAH - High molecular weight PAH.

LPAH - Low molecular weight PAH.

mg/kg - milligram per kilogram.

N - Normal sample.

PAH - Polycyclic Aromatic Hydrocarbon.

PCB - Polychlorinated Biphenyl.

SVOC - Semivolatile organic compound.

TPH - Total Petroleum Hydrocarbon.

U - Not detected.

UJ - The analyte was not detected; and the reporting limit is approximate.

UR - Unreported/rejected.

VOC - Volatile organic compound.

VPH - Volatile Petroleum Hydrocarbons.

(a) Lab calculated value; only used when individual compound data not available.

(b) Total concentrations for use in the risk assessment were calculated per sample by summ
detected individual compounds (i.e., Aroclor/PAH/xylene) concentrations. For samples v
detections of individual compounds (i.e., Aroclor/PAH/xylene), the maximum reporting
limit within the sample is presented as a non-detect value. Calculated totals have a CA
beginning with "RA-".

Notes:
ft - feet.
J - The analyte was detected in the sample at a concentration greater than the instrument detection limit but less than the laboratory practical quantitation limit.
N - Spiked sample recovery not within control limits.
U - The analyte was not detected in the sample at a level greater than the instrument detection limit.
UJ - The analyte was analyzed for but not detected; the sample detection limit is an estimate value.
HPAH - High molecular weight PAH.
LPAH - Low molecular weight PAH.
PAH - Polycyclic aromatic hydrocarbon.
N - Not detected.
mg/kg - milligram per kilogram.
ug/kg - microgram per kilogram.
(a) Total concentrations were calculated per sample by summing only the detected individual compounds concentrations. For samples without any detections of individual compounds, the maximum reporting detection limit within the sample is presented as a non-detect value.
(b) Duplicate sample. Duplicate results were resolved as described in Appendix C.
(c) Background dataset excludes arsenic and lead from sample A-11, lead from sample A-11 offset, and PAHs from sample A-4.

Chromium III concentrations were calculated by the laboratory by subtracting chromium IV from total chromium, and were reported to two significant figures. Where chromium IV was not detected, the chromium III concentration was reported as the total chromium concentration at two significant figures.

Notes:
ID – identification
SDG – sample delivery group

Quality control (QC) validation criteria were derived from the Tier I Sampling And Analysis Plan (SAP) Naval Computer and Telecommunications Area Master Station Atlantic Detachment Cutler, Maine, AECOM, Revision 0, June 2015; the *DoD Quality Systems Manual for Environmental Laboratories, Version 5.0* (July 2013); and USEPA publication: *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods SW846*, (Final Update III, December 1996), specifically SW-846 methods 6010C and 7470 for mercury and SW-846 Methods 5035A/8000B. Validation actions were derived primarily from *USEPA Contract Laboratory Program National Functional Guidelines for Superfund Organic Methods Data Review* (June 2008) and *USEPA Contract Laboratory Program National Functional Guidelines for Inorganic Superfund Data Review, January 2010* and AECOM professional judgment were also considered.

REVIEW ELEMENTS

The data were evaluated based on the following parameters (where applicable to the method):

- ✓ Data completeness (chain-of-custody (COC)/sample integrity
- ✓ Holding times and sample preservation
- ✓ Instrument tuning
- ✓ Initial calibration/continuing calibration verification (specific to methods 8330A
- ✓ Laboratory blanks/trip blanks (VOCs)/equipment blanks
- ✓ Surrogate spike recoveries (specific to methods 8330A)

Any QC nonconformance that resulted in the qualification of data is discussed below. In addition, nonconformances or other issues that were noted during validation, but did not result in qualification of data, may be discussed for informational purposes only.

Based on the scope of the validation, the data are valid as reported and may be used for decision making purposes. Selected data points were estimated and/or negated due to nonconformances of certain QC criteria (see discussion below). No data were rejected as a result of data validation.

ORGANICS RESULTS

1.0 VOLATILES

1.1 Data Completeness

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

1.2 Holding Times/Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The samples were received at the laboratory within the $\leq$6°C temperature criteria. All the samples were analyzed within the 14-day holding time for the preserved samples. The QC acceptance criteria were met.

1.3 Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r^2), and/or response factor method acceptance criteria were met;
- the appropriate number of standards were included in the ICAL;
- the initial calibration verification (ICV) percent recovery (%R) criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met;
- ICAL, ICV and CCVs were analyzed at the appropriate concentration and frequency; and
- The retention time method acceptance criteria were met.

The QC acceptance criteria were met.

1.4 Laboratory Blanks/Equipment Blanks/Trip Blanks

Laboratory method blanks were analyzed at the appropriate frequency of 1 per 20 samples and at least 1 per preparatory batch. Laboratory method blanks, equipment rinsate and trip blanks were evaluated as to whether there were contaminants detected above 1/2 the reporting limit (RL) and above 1/10 the amount measured in any sample or 1/10 the regulatory limit (whichever is greater). For common laboratory contaminants (acetone, 2-butanone and methylene chloride) evaluation was based on analytes detected above the RL, consistent with the Quality control (QC) validation criteria specified in the project SAP.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Method, equipment rinsate, and trip blank results were reviewed for conformance with the QC acceptance criteria. Target analytes detected in blanks are not discussed in this data validation report if the associated results were non-detect or if qualification of sample results was not required.

Trace results for the following samples were blank-qualified as estimated and non-detected (UJ) at the reported concentrations due to sample results less than ten-times the concentrations reported in the associated method blanks: no analytes were detected in trip blanks or method blanks.

1.5 Surrogate Spike Recoveries

Sample FTA-MW-5-091815, FTA-MW-1-091815, and FTA-MW-14-092115-D had high recoveries of the surrogate dibromofluoromethane (SW8260 SIM) which exceeded the acceptance limit of 130%. Since a high recovery which indicated a high bias and there were no target analytes detected above the MDL, no qualification is necessary.

FTA-MW-14-092115, FTA-MW-10-092115, FTA-MW-208-092115, FTA-MW-12-092115, and FTA-DP-35-092115 had high recoveries of the surrogates 1,2-dichloroethane-d4 and dibromofluoromethane (SW8260) which exceeded the acceptance limit of 130%. Since a high recovery which indicated a high bias and there were no target analytes detected above the MDL, no qualification is necessary.

1.6 Matrix Spike/Matrix Spike Duplicates (MS/MSDs)

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria. Project specific MS/MSD %Rs for target analytes were within laboratory control sample acceptance criteria. MS and MSD %Rs were not applicable for samples when native concentrations exceeded 4x the spiked amount. Organic MS/MSD %Rs must both be outside of QC limits in order for organic results to be qualified based on matrix. If organic matrix effect was not confirmed (either MS or MSD was compliant), data did not require qualification. MS/MSD %Rs

from non-project samples were considered, but were not utilized to qualify project samples since matrix similarity to project samples could not be guaranteed.

Sample FTA-MW-210-092115 had high MS/MSD recoveries in isopropylbenzene; however, the LCS was acceptable. No qualification is necessary.

1.7 Laboratory Control Samples/Laboratory Control Sample Duplicates (LCS/LCSDs)

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. An LCS was included in each analytical batch. Recoveries were within QC acceptance criteria specified by DoD QSM v 5.0. All QC acceptance criteria were met except for tetrachloroethene in samples FTA-MW-11-092115 and FTA-MW-14-092115-D. Samples were flagged J.

1.8 Field Duplicate Results

Field duplicate RPDs were reviewed for conformance with a QC acceptance criterion of $\leq$35% for ground water matrices. Field duplicate RPDs were within data validation QC limits, or RPDs were not applicable due to results that were within $\pm$ the reporting limit or were undetected in both samples, except as noted. Field duplicate and native sample concentrations that were both undetected are not reflected as follows since RPDs are not applicable.

1.9 Sample Results/Reporting Issues

Non-detect results were reported at the LOD. All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This J qualifier was retained during data validation.

Any sample that was analyzed at a dilution due to high concentrations of target or non-targets was checked to ensure that the results and/or sample specific LOQs were adjusted accordingly by the laboratory. Reported detection limits are achievable by the quoted methods, and are in compliance with the project requirements. Some samples required dilution due to high concentrations of target analytes or interference. The reporting limits for diluted results were raised appropriately.

2.0 MA VPH

2.1 Data Completeness

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

2.2 Holding Times/Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The samples were received at the laboratory within the $\leq$6°C temperature criteria. All the samples were analyzed within the 28-day holding time for the preserved samples. The QC acceptance criteria were met.

2.3 Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r^2), and/or response factor method acceptance criteria were met;
- the appropriate number of standards were included in the ICAL;
- the initial calibration verification (ICV) percent recovery (%R) criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met;
- ICAL, ICV and CCVs were analyzed at the appropriate concentration and frequency; and
- The retention time method acceptance criteria were met.

The QC acceptance criteria were met.

2.4 Laboratory Blanks/Equipment Blanks/Trip Blanks

Laboratory method blanks were analyzed at the appropriate frequency of 1 per 20 samples and at least 1 per preparatory batch. Laboratory method blanks, equipment rinsate and trip blanks were evaluated as to whether there were contaminants detected above 1/2 the reporting limit (RL) and above 1/10 the amount measured in any sample or 1/10 the regulatory limit (whichever is greater). For common laboratory contaminants (acetone, 2-butanone and methylene chloride) evaluation

was based on analytes detected above the RL, consistent with the Quality control (QC) validation criteria specified in the project SAP.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Method, equipment rinsate, and trip blank results were reviewed for conformance with the QC acceptance criteria. Target analytes detected in blanks are not discussed in this data validation report if the associated results were non-detect or if qualification of sample results was not required.

2.5 Surrogate Spike Recoveries

The surrogate recoveries (%Rs) were reviewed for conformance with the QC acceptance criteria.

2.6 Matrix Spike/Matrix Spike Duplicates (MS/MSDs)

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria. Project specific MS/MSD %Rs for target analytes were within laboratory control sample acceptance criteria.

2.7 Laboratory Control Samples/Laboratory Control Sample Duplicates (LCS/LCSDs)

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. An LCS was included in each analytical batch. Recoveries were within QC acceptance criteria specified by DoD QSM v 5.0. All QC acceptance criteria were met. Data qualification was not required.

2.8 Field Duplicate Results

Field duplicate RPDs were reviewed for conformance with a QC acceptance criterion of $\leq$35% for soil matrices. Field duplicate RPDs were within data validation QC limits, or RPDs were not applicable due to results that were within $\pm$ the reporting limit or were undetected in both samples, except as noted. Field duplicate and native sample concentrations that were both undetected are not reflected as follows since RPDs are not applicable.

2.9 Sample Results/Reporting Issues

Non-detect results were reported at the LOD. All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This J qualifier was retained during data validation.

Any sample that was analyzed at a dilution due to high concentrations of target or non-targets was checked to ensure that the results and/or sample specific LOQs were adjusted accordingly by the laboratory. Reported detection limits are achievable by the quoted methods, and are in compliance with the project requirements. Some samples required dilution due to high concentrations of target analytes or interference. The reporting limits for diluted results were raised appropriately.

ORGANICS RESULTS

3.0 SEMIVOLATILES

3.1 Data Completeness

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

3.2 Holding Times/Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The samples were received at the laboratory within the $\leq$6°C temperature criteria. All the samples were analyzed within the 40-day holding time for the preserved samples. The QC acceptance criteria were met.

3.3 Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r^2), and/or response factor method acceptance criteria were met;
- the appropriate number of standards were included in the ICAL;
- the initial calibration verification (ICV) percent recovery (%R) criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met;
- ICAL, ICV and CCVs were analyzed at the appropriate concentration and frequency; and
- The retention time method acceptance criteria were met.

The QC acceptance criteria were met.

3.4 Laboratory Blanks/Equipment Blanks/Trip Blanks

Laboratory method blanks were analyzed at the appropriate frequency of 1 per 20 samples and at least 1 per preparatory batch. Laboratory method blanks, equipment rinsate and trip blanks were evaluated as to whether there were contaminants detected above 1/2 the reporting limit (RL) and

above 1/10 the amount measured in any sample or 1/10 the regulatory limit (whichever is greater). For common laboratory contaminants (acetone, 2-butanone and methylene chloride) evaluation was based on analytes detected above the RL, consistent with the Quality control (QC) validation criteria specified in the project SAP.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Method, equipment rinsate, and trip blank results were reviewed for conformance with the QC acceptance criteria. Target analytes detected in blanks are not discussed in this data validation report if the associated results were non-detect or if qualification of sample results was not required.

3.5 Surrogate Spike Recoveries

Samples FTA-MW-1-091815, FTA-MW-218-091815 had recoveries for two or more surrogates that were outside the acceptance criteria. The samples were re-extracted within hold time, analyzed, and had similar surrogate deviations. The first set of data was used.

3.6 Matrix Spike/Matrix Spike Duplicates (MS/MSDs)

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria. Project specific MS/MSD %Rs for target analytes were within laboratory control sample acceptance criteria except for 2-METHYLPHENOL and CAPROLACTAM (method SW8270) and 1,1'-BIPHENYL, 2-CHLOROPHENOL, 3,3'-DICHLOROBENZIDINE, BIS(2-ETHYLHEXYL) PHTHALATE, CRESOLS, M & P, DIBENZO(A,H)ANTHRACENE, INDENO(1,2,3-CD)PYRENE, and N-NITROSO-DI-N-PROPYLAMINE in sample FTA-MW-210-092115. These analytes were qualified J.

3.7 Laboratory Control Samples/Laboratory Control Sample Duplicates (LCS/LCSDs)

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. An LCS was included in each analytical batch. Recoveries were within QC acceptance criteria specified by DoD QSM v 5.0. All QC acceptance criteria were met except for 2-methylphenol and caprolactam (method SW8270) in samples FTA-DP-35-092115, FTA-MW-10-092115, FTA-MW-1-091815, FTA-MW-12-092115, FTA-MW-14-092115, FTA-MW-14-092115-D, FTA-MW-206-091815, FTA-MW-206-091815-D, and FTA-MW-218-091815. All QC acceptance criteria were met except for 1,1'-biphenyl (method SW8270_SIM) in samples FTA-DP-35-092115, FTA-MW-10-092115, FTA-MW-1-091815, FTA-MW-12-092115, FTA-MW-14-092115, FTA-MW-14-092115-D, FTA-MW-206-091815, FTA-MW-206-091815-D, FTA-MW-218-091815, FTA-MW-5-091815, and FTA-MW-9-091515. Samples were flagged J.

3.8 Field Duplicate Results

Field duplicate RPDs were reviewed for conformance with a QC acceptance criterion of $\leq$35% for ground water matrices. Field duplicate RPDs were within data validation QC limits, or RPDs were

not applicable due to results that were within $\pm$ the reporting limit or were undetected in both samples, except as noted. Field duplicate and native sample concentrations that were both undetected are not reflected as follows since RPDs are not applicable.

3.9 Sample Results/Reporting Issues

Non-detect results were reported at the LOD. All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This J qualifier was retained during data validation.

Any sample that was analyzed at a dilution due to high concentrations of target or non-targets was checked to ensure that the results and/or sample specific LOQs were adjusted accordingly by the laboratory. Reported detection limits are achievable by the quoted methods, and are in compliance with the project requirements. Some samples required dilution due to high concentrations of target analytes or interference. The reporting limits for diluted results were raised appropriately.

4.0 MA EPH

4.1 Data Completeness

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

4.2 Holding Times/Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The samples were received at the laboratory within the $\leq$6°C temperature criteria. All the samples were analyzed within the 40-day holding time for the preserved samples. The QC acceptance criteria were met.

4.3 Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r^2), and/or response factor method acceptance criteria were met;
- the appropriate number of standards were included in the ICAL;
- the initial calibration verification (ICV) percent recovery (%R) criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met;
- ICAL, ICV and CCVs were analyzed at the appropriate concentration and frequency; and
- The retention time method acceptance criteria were met.

The QC acceptance criteria were met.

4.4 Laboratory Blanks/Equipment Blanks/Trip Blanks

Laboratory method blanks were analyzed at the appropriate frequency of 1 per 20 samples and at least 1 per preparatory batch. Laboratory method blanks, equipment rinsate and trip blanks were evaluated as to whether there were contaminants detected above 1/2 the reporting limit (RL) and above 1/10 the amount measured in any sample or 1/10 the regulatory limit (whichever is greater). For common laboratory contaminants (acetone, 2-butanone and methylene chloride) evaluation

was based on analytes detected above the RL, consistent with the Quality control (QC) validation criteria specified in the project SAP.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Method, equipment rinsate, and trip blank results were reviewed for conformance with the QC acceptance criteria. Target analytes detected in blanks are not discussed in this data validation report if the associated results were non-detect or if qualification of sample results was not required.

4.5 Surrogate Spike Recoveries

Sample FTA-MW-14-092115, FTA-MW-14-092115-D, and FTA-DP-35-092115 had low recoveries for the extraction surrogate 5-alpha androstane. The samples were re-extracted within hold time with similar deviations confirming a matrix effect. The first set of data was used.

4.6 Matrix Spike/Matrix Spike Duplicates (MS/MSDs)

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria. Project specific MS/MSD %Rs for target analytes were within laboratory control sample acceptance criteria.

4.7 Laboratory Control Samples/Laboratory Control Sample Duplicates (LCS/LCSDs)

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. An LCS was included in each analytical batch. Recoveries were within QC acceptance criteria specified by DoD QSM v 5.0. All QC acceptance criteria were met. Data qualification was not required.

4.8 Field Duplicate Results

Field duplicate RPDs were reviewed for conformance with a QC acceptance criterion of $\leq$35% for ground water matrices. Field duplicate RPDs were within data validation QC limits, or RPDs were not applicable due to results that were within $\pm$ the reporting limit or were undetected in both samples, except as noted. Field duplicate and native sample concentrations that were both undetected are not reflected as follows since RPDs are not applicable.

4.9 Sample Results/Reporting Issues

Non-detect results were reported at the LOD. All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This J qualifier was retained during data validation.

Any sample that was analyzed at a dilution due to high concentrations of target or non-targets was checked to ensure that the results and/or sample specific LOQs were adjusted accordingly by the laboratory. Reported detection limits are achievable by the quoted methods, and are in compliance

with the project requirements. Some samples required dilution due to high concentrations of target analytes or interference. The reporting limits for diluted results were raised appropriately.

This page intentionally left blank.

5.0 POLYCHLORINATED BIPHENYLS

5.1 Data Completeness

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

5.2 Holding Times/Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The samples were received at the laboratory within the $\leq$6°C temperature criteria. All the samples were analyzed within the 40-day holding time for the preserved samples. The QC acceptance criteria were met.

5.3 Initial Calibration/Continuing Calibration Verification

Calibration data were reviewed for conformance with the QC acceptance criteria to ensure that:

- the initial calibration (ICAL) percent relative standard deviation (%RSD), correlation coefficient (r)/coefficient of determination (r^2), and/or response factor method acceptance criteria were met;
- the appropriate number of standards were included in the ICAL;
- the initial calibration verification (ICV) percent recovery (%R) criteria were met;
- the continuing calibration verification standard (CCV) method percent difference or percent drift (%Ds) and RF acceptance criteria were met;
- ICAL, ICV and CCVs were analyzed at the appropriate concentration and frequency; and
- The retention time method acceptance criteria were met.

The QC acceptance criteria were met.

5.4 Laboratory Blanks/Equipment Blanks/Trip Blanks

Laboratory method blanks were analyzed at the appropriate frequency of 1 per 20 samples and at least 1 per preparatory batch. Laboratory method blanks, equipment rinsate and trip blanks were evaluated as to whether there were contaminants detected above 1/2 the reporting limit (RL) and above 1/10 the amount measured in any sample or 1/10 the regulatory limit (whichever is greater). For common laboratory contaminants (acetone, 2-butanone and methylene chloride) evaluation

was based on analytes detected above the RL, consistent with the Quality control (QC) validation criteria specified in the project SAP.

Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Method, equipment rinsate, and trip blank results were reviewed for conformance with the QC acceptance criteria. Target analytes detected in blanks are not discussed in this data validation report if the associated results were non-detect or if qualification of sample results was not required.

5.5 Surrogate Spike Recoveries

The surrogate recoveries (%Rs) were reviewed for conformance with the QC acceptance criteria.

5.6 Matrix Spike/Matrix Spike Duplicates (MS/MSDs)

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria. Project specific MS/MSD %Rs for target analytes were within laboratory control sample acceptance criteria.

5.7 Laboratory Control Samples/Laboratory Control Sample Duplicates (LCS/LCSDs)

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. An LCS was included in each analytical batch. Recoveries were within QC acceptance criteria specified by DoD QSM v 5.0. All QC acceptance criteria were met. Data qualification was not required.

5.8 Field Duplicate Results

Field duplicate RPDs were reviewed for conformance with a QC acceptance criterion of $\leq$35% for ground water matrices. Field duplicate RPDs were within data validation QC limits, or RPDs were not applicable due to results that were within $\pm$ the reporting limit or were undetected in both samples, except as noted. Field duplicate and native sample concentrations that were both undetected are not reflected as follows since RPDs are not applicable.

5.9 Sample Results/Reporting Issues

Non-detect results were reported at the LOD. All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This J qualifier was retained during data validation.

Any sample that was analyzed at a dilution due to high concentrations of target or non-targets was checked to ensure that the results and/or sample specific LOQs were adjusted accordingly by the laboratory. Reported detection limits are achievable by the quoted methods, and are in compliance with the project requirements. Some samples required dilution due to high concentrations of target analytes or interference. The reporting limits for diluted results were raised appropriately.

INORGANIC RESULTS

6.0 METALS (6010C)

6.1 Data Completeness

The data package was reviewed and found to meet acceptance criteria for completeness:

- The COCs were reviewed for completeness of information relevant to the samples and requested analyses, and for signatures indicating transfer of sample custody.
- The laboratory sample login sheet(s) were reviewed for issues potentially affecting sample integrity, including the condition of sample containers upon receipt at the laboratory.
- Completeness of analyses was verified by comparing the reported results to the COC requests.

6.2 Holding Times/Sample Preservation

Sample preservation and preparation/analysis holding times were reviewed for conformance with the QC acceptance criteria. The samples were received at the laboratory within the $\leq$6°C temperature criteria, preserved with HNO3 to pH <2. All the samples were analyzed within the 180-day holding time (28 days for Hg) for the preserved samples. The QC acceptance criteria were met.

6.3 ICP Performance Checks

The data were reviewed to ensure that the Inductively Coupled Plasma (ICP) tune was performed at the correct frequency and that the method acceptance criteria were met. The Percent Relative Standard Deviation (%RSD) of the absolute signal for all 6010C analytes in the tuning solution were < 5%. The QC acceptance criteria were met.

6.4 Laboratory Blanks/Equipment Blanks

Laboratory method blanks and equipment rinsate blanks were evaluated as to whether there were contaminants detected above 1/2 the reporting limit (RL) and above 1/10 the amount measured in any sample or 1/10 the regulatory limit (whichever is greater). Data validation qualifications for individual samples are based on the maximum contaminant concentration detected in all associated blanks.

Method and equipment rinsate results were reviewed for conformance with the QC acceptance criteria. Detected results in blanks are not discussed in this data validation report if the associated results were or if qualification of sample results was not required.

6.5 Matrix Spike/Matrix Spike Duplicates (MS/MSDs)

The MS/MSD %Rs and relative percent differences (RPDs) were reviewed for conformance with the QC acceptance criteria. Project specific MS/MSD %Rs for target analytes were within SAP specified

QC limits of 80-120% for metal analytes, or MS/MSD data met the following requirements, except calcium (FTA-MW-210-ground water092115); flagged J+.

6.6 Laboratory Control Samples/Laboratory Control Sample Duplicates (LCS/LCSDs)

The LCS/LCSD %Rs and/or RPDs were reviewed for conformance with the QC acceptance criteria. An LCS was included in each analytical batch. Recoveries were within QC acceptance criteria specified by DoD QSM v 5.0. All QC acceptance criteria were met. Data qualification was not required.

6.7 Field Duplicate Results

Field duplicate RPDs were reviewed for conformance with a QC acceptance criterion of $\leq$35% for groundwater matrices. Field duplicate RPDs were within data validation QC limits, or RPDs were not applicable due to results that were within $\pm$ the reporting limit or were undetected in both samples, except as noted.

6.8 Sample Results/Reporting Issues

Non-detect results were reported at the LOD. All compounds detected at concentrations less than the LOQ but greater than the DL were qualified by the laboratory as estimated (J). This J qualifier was retained during data validation.

Any sample that was analyzed at a dilution due to high concentrations of target or non-targets was checked to ensure that the results and/or sample specific LOQs were adjusted accordingly by the laboratory. Reported detection limits are achievable by the quoted methods, and are in compliance with the project requirements. Some samples required dilution due to high concentrations of target analytes or interference. The reporting limits for diluted results were raised appropriately.

The post-digestion spiked sample recovery of lead in sample FTA-MW-210-092115 was not within control limits. The sample was flagged J+.

SDG	Method	Unit	Analyte	LOQ	RPD	FTA-MW-14-092115 (S17420-6)	FTA-MW-14-092115-D (S17420-16)	Qualifier	RPD Limit

7.0 PRECISION, ACCURACY, METHOD COMPLIANCE, AND COMPLETENESS ASSESSMENT

7.1 Precision

Precision is the measure of variability between individual sample measurements. Field precision was determined by comparison of field duplicate sample results (where applicable). Laboratory precision was determined by examination of laboratory duplicate results. MS/MSD pairs measure both field and laboratory precision. Evaluation of duplicates for precision was done using the Relative Percent Difference (RPD). The RPD is defined as the difference between two duplicate samples divided by the mean and expressed as a percent. RPD limits referenced SAP published QC limits. Data that required qualification based calculated field duplicate RPDs, are discussed in **Section 1.0**. Overall field and laboratory precision is acceptable since majority of the data is unqualified and no data is rejected based on these measurements.

7.2 Accuracy

Field accuracy, a measure of the sampling bias, was determined by reviewing field blank and trip blank results for evidence of sample contamination stemming from sampling activities and/or sample transport/bottle contamination. Laboratory accuracy is a measure of the system bias, and was measured by evaluating laboratory control sample/laboratory control sample duplicate (LCS/LCSD), matrix spike/matrix spike duplicate (MS/MSD), and organic system monitoring compounds (surrogate) percent recoveries (%Rs). LCS/LCSD %Rs, which demonstrated the overall performance of the analytical procedure, were compared to published or recommended SAP QC limits. MS/MSD %Rs, which provided information on sample matrix interferences were compared to SAP published QC limits or laboratory control charted limits. System monitoring compound or surrogate recoveries, which measured system performance and efficiency during organic analysis, were compared to SAP published QC limits. Data that required qualification based on surrogate, matrix spike, or other outliers are discussed in **Section 1.0**. Overall field and laboratory accuracy is acceptable since majority of the data is unqualified and no data is rejected based on these measurements.

7.3 Compliance

For this sample set, method compliance was determined by evaluating sample integrity, preservation, holding time, laboratory blanks and calibration against method specified requirements, while applying EPA data validation guidelines. No data require qualification based on method compliance measurements and overall method compliance is acceptable based on the data reported.

7.4 Completeness

Completeness is the overall ratio of the number of samples planned versus the number of samples with valid analyses. Completeness goals are set at 90-100%. Determination of completeness included a review of chain of custody records, laboratory analytical methods and detection limits,

laboratory case narratives and project requirements. Completeness also included 100% review of the laboratory sample data results and electronic data deliverables (EDDs).

All reported data was usable with qualification and the completeness of the data set was calculated to be within the set goal of 90% -100% and determined to be acceptable.

Qualifier Codes and Explanations

Qualifier	Explanation
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
J+	The result is an estimated quantity, but the result may be biased high.
J-	The result is an estimated quantity, but the result may be biased low.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
U	The analyte was analyzed for but was not detected above the reported sample quantitation limit.
R	The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

APPENDIX C

BACKGROUND EVALUATION

This page intentionally left blank.

TABLE OF CONTENTS

TABLES

ATTACHMENTS

1.0 INTRODUCTION

This appendix presents an evaluation of chemicals of potential concern (COPCs), identified based on the Ecological Risk Assessment (ERA) and/or the Human Health Risk Assessment (HHRA) for the Fire Training Area (Site 1) located at the Naval Computer and Telecommunications Area Master Station Atlantic Detachment (NCTAMS LANT Det) in Cutler, Maine, in available background media samples. This background evaluation was conducted using the following guidance:

- Navy Guidance for Environmental Background Analysis, Volume I: Soil (Naval Facilities Engineering Command [NAVFAC], 2002)
- Navy Guidance for Environmental Background Analysis, Volume II: Sediment (NAVFAC, 2003)

The ERA and/or HHRA determined several COPCs that warrant an evaluation for consistency with background conditions. Surface soil, surface water, and surface sediment COPCs that may pose potential risk to plants, invertebrates, and/or wildlife are summarized in **Table 10** in the ERA. Surface soil, subsurface soil, groundwater, surface water, and surface sediment COPCs that may pose potential risk to human health receptors are shown in **Table 2.7** in the HHRA. The COPCs identified in **Table 10** in the ERA and **Table 2.7** in the HHRA were evaluated for consistency with background conditions with the exception of the following parameters that were not measured in background samples:

- Acetone, 1,1-biphenyl, bis(2-ethylhexylphthalate), carbazole, carbon disulfide, dibenzofuran, dichlorodifluoromethane, and methyl acetate in surface soil.
- Vinyl chloride in subsurface soil.
- COPCs in groundwater.
- Total polychlorinated biphenyls (PCB) (aroclors), benzo(b)fluoranthene, thallium, 4,4-dichlorodiphenyldichloroethane (DDD), 4,4-dichlorodiphenyldichloroethylene (DDE), 4,4-dichlorodiphenyltrichloroethane (DDT), dieldrin, endosulfan sulfate, endrin aldehyde, endrin ketone, 1,4-dioxane, 2,4-nitrotoluene, bis(2-ethylhexyl)phthalate, carbazole, dibenzofuran, acetone, cis-1,2-dichloroethene, methyl cyclohexane, and toluene in sediment.
- Total arsenic, total copper, total thallium, total PCB (aroclors), 1,2,4,5-tetrachlorobenzene, benzo(a)anthracene, benzo(a)pyrene, benzo(k)fluoranthene, bis(2-chloroethyl)ether, indeno(1,2,3-cd)pyrene, and toluene in surface water.

This document is organized as follows:

- Section 2.0 – A summary of the background data available that were included in this evaluation for each media type.
- Section 3.0 – For each media type, the methodology for comparing site to background is presented.
- Section 4.0 – The results of the background comparisons are presented for each media type and when applicable, each exposure area of the site.
- Section 5.0 – The conclusions of the background evaluation are presented.

2.0 SUMMARY OF BACKGROUND DATA

The following is a summary of the background soil, sediment, and surface water data that were used in this evaluation.

2.1 Soil

Background soils data (0-1 ft below ground surface [bgs]) collected as part of the Background Study for Remedial Investigations for Installation Restoration Sites at NCTAMS LANT Det in Cutler, Maine ("Background Study"; Battelle, 2005) were included in this evaluation. The Background Study included samples collected and analyzed for metals and polycyclic aromatic hydrocarbons (PAHs) at 15 locations in each of the two primary soil types (glacial till and glacio-marine sediments) and for PCBs (as aroclors), pesticides, and herbicides at 20 locations in the high frequency antenna area that are used to represent background conditions. Analytical methods used for the Background Study (Battelle, 2005) are consistent with those used for site soil. Analytical results for background soils are presented in **Appendix A** of the RI Report and summary statistics for the COPCs that were measured in background soils are presented in **Table 1**.

For metals except arsenic, copper, and lead, all background soils data were used. Per the Background Study (Battelle, 2005), the following arsenic, copper, and lead results were excluded:

- Arsenic results from location A-11
- Copper results from locations A-11 and A-11 Offset
- Lead results from locations A-11 and A-11 Offset

The Background Study (Battelle, 2005) concluded the metals concentrations in these samples were unusually high relative to other background samples and recommended the sample results should be excluded.

For PAHs, all background soils data were used except sample A-4. Per the Background Study (Battelle, 2005), several PAHs from sample A-4 were elevated compared to other samples and should be excluded. For PCBs, pesticides, and herbicides all background soils data were used.

Background soil data for PAHs and pesticides COPCs were compiled from the Background Study (Battelle, 2005) for use in the background evaluation. During data compilation duplicates were resolved as follows: 1) where both the sample and the duplicate are not detected, the resulting value is the average of the limits of detection; 2) where both the sample and the duplicate are detected, the resulting value is the average of the detected results; and 3) where one of the pair is reported as not detected and the other is detected, the detected concentration is used. PAHs from the Background Study were also summed to calculate total high molecular weight (HMW) and low molecular weight (LMW) PAHs as follows:

- For samples with at least one detect, only the detected results were summed to calculate the total concentration.
- Where a sample does not have any detections of individual chemicals, then the total concentration was considered a non-detect with a limit of detection equal to the maximum limit of detection of the individual chemicals.

2.2 Sediment

Sediment samples collected from within the top 0-1 ft bgs as part of the Salvage Yard Area remedial investigation were identified as background sediment samples. Background sediment samples SD-R04, SD-R05, and SD-R06 were included in this evaluation. Copper results from SD-R04 were not included per the June 2, 2014 letter from Tetra Tech to Maine Department of Environmental Protection (DEP) providing the final meeting notes from a conference call held on February 26, 2014 among Maine DEP, United States Environmental Protection Agency (USEPA), Tetra Tech, and the Navy in regard to appropriate selection of background sediment samples for the Very Low Frequency area of NCTAMS LANT Det. Analytical results for background sediments are presented in **Appendix A** of the RI Report and summary statistics for the COPCs that were measured in background sediment are presented in **Table 2**.

2.3 Surface Water

Background surface water samples SW-R04, SW-R05, and SW-R06 were collected as part of the Salvage Yard Area remedial investigation and were identified as background surface water samples for this evaluation. Analytical results for background surface water are presented in **Appendix A** of the RI Report and summary statistics for the COPCs that were measured in background surface water are presented in **Table 3**.

3.0 BACKGROUND EVALUATION METHODOLOGY

3.1 Soil

Both site surface soil, defined as 0-2 ft bgs, and site subsurface soil, defined as >2 ft bgs, were compared to the background soils data collected from 0-1 ft bgs. For surface soil, site concentrations of COPCs were compared to background concentrations using three separate site datasets. The first dataset includes site surface soil samples collected from Exposure Area 1, the second dataset includes site surface soil samples collected from Exposure Area 2, and the third dataset combines all site surface soil samples. Surface soil COPCs based on the HHRA are by exposure area, where as surface soil COPCs based on the ERA are site-wide.

For surface and subsurface soil, site and background data were compared using statistical techniques when adequate data were available, and using graphical comparisons for data sets with few samples or low frequency of detection. When either the background and site datasets had frequencies of detection less than 60%, consistency between site and background concentrations was evaluated only based on graphical comparisons. In cases where all background concentrations were not detected for a particular COPC, no evaluation was conducted.

Concentrations for all valid comparisons (i.e., there were detections in the background data) were first evaluated graphically (see **Attachments 1** to **6** for graphs of surface soil and **Attachments 7** to **10** for graphs of subsurface soil) with boxplots, histograms, and cumulative percentage plots. Boxplots and cumulative percentage plots were used to compare both concentrations and natural log transformed concentrations. Cumulative percentage plots were also used to compare detection limits in the site and background datasets. On the cumulative percentage plots detected concentrations are shown with a different symbol than non detected concentrations.

A statistical comparison between site and background surface soil data was then conducted using USEPA's ProUCL software, version 5.1.002 (USEPA, 2016a). Per the Navy Guidance for Environmental Background Analysis (NAVFAC, 2002 & NAVFAC, 2003) the t-test is only appropriate if less than 15% of measurements are below detection and the Gehan and WMW tests are only appropriate if no more than 40% of both the site and background dataset are non detects. As a result two-sample hypothesis tests were only run on concentrations if both background and site datasets had frequencies of detection greater than 60%.

A two-sample hypothesis test was conducted to compare the mean or median of site and background datasets. The null hypothesis (H_O) and alternative hypothesis (H_A) of this test are:

H_O = Mean/Median of Site Concentrations <= Background Concentrations

H_A = Mean/Median of Site Concentrations > Background Concentrations

The statistical tests selected for each COPC was determined by the distributions of the site and background soil datasets. Tests were conducted using untransformed data only; log- or other transformations were not considered in the statistical tests. This is consistent with the ProUCL Version 5.1.002 Technical Guidance (USEPA, 2016b) which recommends that a t-test not be used on log-transformed data sets on the basis that a t-test on log transformed datasets tests the equality of medians and not the equality of means. The normality of the distributions was determined using Goodness-of-Fit Statistics (Shapiro-Wilk test when available otherwise Lilliefors test, significance level 0.05, normal regression on order statistic estimates for non-detects) in ProUCL 5.1.002. If both datasets were all detected samples with normal distributions, then a t-test was selected. If either datasets were not normally distributed or both datasets were normally distributed, however, not all samples had detected concentrations, then the non-parametric Wilcoxon-Mann Whitney (WMW) or Gehan test was selected. The WMW test was selected in cases of datasets including all detected samples (with not normal distributions), or in cases of datasets with non-detected concentrations where the detection limits were equal. The Gehan test was selected in the case of datasets that included non-detected samples with unequal detection limits.

If the p-value of the two-sample hypothesis test was greater than alpha (0.05), then the null hypothesis was not rejected and it was concluded that site concentrations are less than or equal to background concentrations. If the p-value was less than alpha (0.05), then the null hypothesis was rejected and the alternative hypothesis was accepted: site concentrations are greater than background concentrations.

3.2 Sediment and Surface Water

For sediment and surface water, there were only three background samples available for each. At least 10 site and background samples are required to run a statistical comparison (USEPA, 2016b). As a result, site and background concentrations were evaluated graphically by showing a boxplot for site data adjacent to a stacked dotplot of background data (see **Attachment 11** for graphs of sediment and **Attachment 12** for graphs of surface water). Where all background concentrations were not detected, no graphical comparison was conducted.

4.0 BACKGROUND EVALUATION RESULTS

The following section presents the results of the background evaluation for each media type. The results of the statistical comparisons are presented in tabular form. The graphical comparisons are presented in **Attachments 1-12**. The ProUCL output is presented in **Attachment 13**.

4.1 Surface Soil – Exposure Area 1

Table 4 shows Exposure Area 1 site surface soil and background soil frequencies of detection along with the two-sample hypothesis test results and graphical comparisons are presented in **Attachments 1-2**. Frequencies of detection in **Table 4** show that total PCB (aroclors) were not

detected in background, but were a COPC in Exposure Area 1. Therefore, a comparison of site and background total PCB (aroclors) in surface soil was not conducted for Exposure Area 1.

4.1.1 Quantitative Evaluation of Surface Soil COPCs – Exposure Area 1

The two-sample hypothesis test results comparing site surface soil and background soil concentrations are presented in **Table 4** for the seven COPCs in Exposure Area 1 with adequate data to conduct quantitative comparisons:

- Aluminum, arsenic, total chromium, cobalt, iron, manganese, and vanadium.

The remaining two site surface soil COPCs that were measured in background samples had frequencies of detection less than 60% in site and/or background surface soil, and therefore, quantitative comparisons were not conducted for:

- Thallium and benzo(a)pyrene.

Based on the Shapiro-Wilk test, the distributions of site surface soil datasets are normal except cobalt, iron, and manganese. For background soil datasets four COPCs were normally distributed (aluminum, total chromium, iron, and vanadium). The remaining three COPCs were not normally distributed (arsenic, cobalt, and manganese) in background.

Datasets that included 100% frequency of detection (with not normal distributions) or where detection limits (> 60% detect) were equal were evaluated using the WMW test. Five COPCs were evaluated using the WMW test. The results of the WMW tests are as follows:

- Null hypothesis not rejected: site concentrations of arsenic, total chromium, and iron are less than or equal to background concentrations.
- Null hypothesis rejected: site concentrations of cobalt and manganese are greater than background concentrations.

Aluminum and vanadium concentrations were all detected with normal distributions in both the site and background datasets. As a result the t-test was run with the following results:

- Null hypothesis not rejected: site concentrations of aluminum and vanadium are less than or equal to background concentrations.

Attachment 1 includes graphs for the COPCs which were evaluated with two-sample hypothesis tests. The graphs of COPCs which were evaluated with two-sample hypothesis tests support the test results.

4.1.2 Qualitative Evaluation of Surface Soil COPCs – Exposure Area 1

Qualitative evaluations (i.e., graphical comparisons) were conducted for those COPCs in Exposure Area 1 with low frequency of detection. **Attachment 2** presents graphs for the following COPCs that had <60% frequency of detection:

- Thallium and benzo(a)pyrene.

The cumulative percentage plots of thallium show that background concentrations (red dots) were not detected except in one sample, while site concentrations (blue dots) were detected in all samples. The cumulative percentage plots also show that background detection limits are higher than detected site concentrations. Given the elevated detection limits in background samples, conclusions based on a qualitative evaluation cannot be drawn.

The cumulative percentage plots of benzo(a)pyrene show low frequencies of detection in site and background concentrations. The cumulative percentage plots also show that detection limits are higher in background concentrations than site concentrations.

4.2 Surface Soil – Exposure Area 2

Table 4 shows Exposure Area 2 site surface soil and background soil frequencies of detection along with the two-sample hypothesis test results and graphical comparisons are presented in **Attachments 3-4**. Frequencies of detection in **Table 4** show that the following five COPCs were not detected in background, but were detected in Exposure Area 2:

- Dieldrin, endrine ketone, heptachlor epoxide, total PCBs (aroclors), and dibenz(a,h)anthracene.

For these COPCs, no evaluations were conducted.

4.2.1 Quantitative Evaluation of Surface Soil COPCs – Exposure Area 2

The two-sample hypothesis test results comparing site surface soil and background soil concentrations are presented in **Table 4** for the seven COPCs in Exposure Area 2 with adequate data to conduct quantitative comparisons:

- Aluminum, arsenic, total chromium, cobalt, iron, manganese, and vanadium.

The remaining six site surface soil COPCs that were measured in background samples had frequencies of detection less than 60% in site and/or background surface soil, and therefore, quantitative comparisons were not conducted for:

- Thallium, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, and indeno(1,2,3-cd)pyrene.

Based on the Shapiro-Wilk test, the distributions of site surface soil datasets are normal. For background soil datasets four COPCs were normally distributed (aluminum, total chromium, iron, and vanadium). The remaining three COPCs were not normally distributed (arsenic, cobalt, and manganese) in background.

Datasets that included 100% frequency of detection (with not normal distributions) or where detection limits (> 60% detect) were equal were evaluated using the WMW test. Three COPCs were evaluated using the WMW test. The results of the WMW tests are as follows:

- Null hypothesis not rejected: site concentrations of arsenic are less than or equal to background concentrations.
- Null hypothesis rejected: site concentrations of cobalt and manganese are greater than background concentrations.

Datasets that were all detected samples with normal distributions in both the site and background datasets were evaluated using the t-test. Four COPCs were evaluated using the t-test. The results of the t-tests are as follows:

- Null hypothesis not rejected: site concentrations of aluminum, iron, and vanadium are less than or equal to background concentrations; and
- Null hypothesis rejected: site concentrations of total chromium are greater than background concentrations.

Attachment 3 includes graphs for the COPCs which were evaluated with two-sample hypothesis tests. The graphs of COPCs which were evaluated with two-sample hypothesis tests support the test results.

4.2.2 Qualitative Evaluation of Surface Soil COPCs – Exposure Area 2

Qualitative evaluations (i.e., graphical comparisons) were conducted for those COPCs in Exposure Area 2 with low frequency of detection. **Attachment 4** presents graphs for the following COPCs that had <60% frequency of detection:

- Thallium, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, and indeno(1,2,3-cd)pyrene.

The cumulative percentage plots of thallium show that background concentrations (red dots) were not detected except in one sample, while site concentrations (blue dots) were detected in all but one sample. The cumulative percentage plots also show that background detection limits are higher than detected site concentrations. Given the elevated detection limits in background samples, conclusions based on a qualitative evaluation cannot be drawn.

The cumulative percentage plots of benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene and indeno(1,2,3-cd)pyrene show low frequencies of detection in site and background concentrations. The cumulative percentage plots also show that detection limits are higher in background concentrations than site concentrations for these COPCs except benzo(k)fluoranthene. Detection limits are higher in site concentrations than background concentrations for benzo(k)fluoranthene.

The graphs of benzo(a)anthracene show low frequencies of detection in site and background concentrations. The range of site surface soil concentrations overlaps with background soil concentrations, but detected site surface soil concentrations are higher than detected background concentrations.

4.3 Surface Soil – Site-Wide

Table 4 shows site-wide surface soil and background soil frequencies of detection along with the two-sample hypothesis test results and graphical comparisons are presented in **Attachments 5-6**. Frequencies of detection in **Table 4** show that the following 10 COPCs were not detected in background, but were detected on site:

- Dieldrin, endosulfan I, endosulfan II, endosulfan sulfate, endrin, endrin aldehyde, endrine ketone, heptachlor epoxide, methoxychlor, and total PCBs (aroclors).

For these COPCs no evaluations were conducted.

4.3.1 Quantitative Evaluation of Surface Soil COPCs – Site-Wide

The two-sample hypothesis test results comparing site surface soil and background soil concentrations are presented in **Table 4** for the 10 site-wide COPCs with adequate data to conduct quantitative comparisons:

- Cadmium, total chromium, cobalt, lead, manganese, mercury, selenium, vanadium, zinc, and total HMW PAHs.

The remaining two site surface soil COPCs that were measured in background samples had frequencies of detection less than 60% in site and/or background surface soil, and therefore, quantitative comparisons were not conducted for:

- 4,4-DDT and total LMW PAHs.

Based on the Shapiro-Wilk test, the distributions of site surface soil datasets are not normal except total chromium, vanadium, and zinc. For background soil datasets six COPCs were normally distributed (cadmium, total chromium, lead, mercury, vanadium, and zinc). The remaining four

COPCs were not normally distributed (cobalt, manganese, selenium, and total HMW PAHs) in background.

Datasets that included 100% frequency of detection (with not normal distributions) or where detection limits (> 60% detect) were equal were evaluated using the WMW test. Four COPCs were evaluated using the WMW test. The results of the WMW tests are as follows:

- Null hypothesis not rejected: site concentrations of lead are less than or equal to background concentrations.
- Null hypothesis rejected: site concentrations of total chromium, cobalt, and manganese are greater than background concentrations.

Datasets that included 100% frequency of detection with normal distributions in both the site and background datasets were evaluated using the t-test. Two COPCs were evaluated using the t-test. The results of the t-tests are as follows:

- Null hypothesis not rejected: site concentrations of vanadium are less than or equal to background concentrations; and
- Null hypothesis rejected: site concentrations of zinc are greater than background concentrations.

Datasets that included non-detected samples with unequal detection limits were evaluated using the Gehan test. Four COPCs were evaluated using the Gehan test. The results of the Gehan tests are as follows:

- Null hypothesis not rejected: site concentrations of cadmium, mercury, and selenium are less than or equal to background concentrations.
- Null hypothesis rejected: site concentrations of total HMW PAHs are greater than background concentrations.

Attachment 5 includes graphs for the COPCs which were evaluated with two-sample hypothesis tests. The graphs of COPCs which were evaluated with two-sample hypothesis tests support the test results.

4.3.2 Qualitative Evaluation of Surface Soil COPCs – Site-Wide

Qualitative evaluations (i.e., graphical comparisons) were conducted for those COPCs with low frequency of detection. **Attachment 6** presents graphs for the following COPCs that had <60% frequency of detection:

4,4-DDT and total LMW PAHs.

The cumulative percentage plots of 4,4-DDT show that background concentrations (red dots) were not detected except in one sample, while site concentrations (blue dots) were detected in ten samples. The cumulative percentage plots also show that detection limits are higher in site concentrations than background concentrations.

The cumulative percentage plots of total LMW PAH show low frequencies of detection in site and background concentrations. The cumulative percentage plots also show that detection limits are higher in site concentrations than background concentrations.

4.4 Subsurface Soil – Exposure Area 1

Table 5 shows Exposure Area 1 subsurface soil and background soil frequencies of detection along with the two-sample hypothesis test results and graphical comparisons are presented in **Attachments 7-8**.

4.4.1 Quantitative Evaluation of Subsurface Soil COPCs – Exposure Area 1

The two-sample hypothesis test results comparing site subsurface soil and background soil concentrations are presented in **Table 5** for the following seven COPCs in Exposure Area 1 with adequate data to conduct quantitative comparisons:

- Aluminum, arsenic, total chromium, cobalt, iron, manganese, and vanadium.

The remaining COPC that was measured in background samples, thallium, had a frequency of detection less than 60% in site and/or background subsurface soil, and therefore, quantitative comparisons were not conducted for thallium.

Based on the Shapiro-Wilk test, the distributions of site subsurface soil datasets are normal except manganese and vanadium. For background soil datasets four COPCs were normally distributed (aluminum, total chromium, iron, and vanadium). The remaining three COPCs were not normally distributed (arsenic, cobalt, and manganese) in background.

Datasets that included 100% frequency of detection (with not normal distributions) or where detection limits (> 60% detect) were equal were evaluated using the WMW test. Five COPCs were evaluated using the WMW test. The results of the WMW tests are as follows:

- Null hypothesis not rejected: site concentrations of arsenic and vanadium are less than or equal to background concentrations.
- Null hypothesis rejected: site concentrations of total chromium, cobalt, and manganese are greater than background concentrations.

Datasets that included 100% frequency of detection with normal distributions in both the site and background datasets were evaluated using the t-test. Two COPCs were evaluated using the t-test. The results of the t-tests are as follows:

- Null hypothesis not rejected: site concentrations of aluminum and iron are less than or equal to background concentrations.

Attachment 7 includes graphs for the COPCs which were evaluated with two-sample hypothesis tests. The graphs of COPCs which were evaluated with two-sample hypothesis tests support the test results.

4.4.2 Qualitative Evaluation of Subsurface Soil COPCs – Exposure Area 1

Qualitative evaluations (i.e., graphical comparisons) were conducted for those COPCs in Exposure Area 1 with low frequency of detection. **Attachment 8** presents graphs for the following COPC in Exposure Area 1 that had <60% frequency of detection:

- Thallium.

The cumulative percentage plots of thallium show that background concentrations (red dots) were not detected except in one sample, while site concentrations (blue dots) were detected in all but one sample. The cumulative percentage plots also show that background detection limits are higher than detected site concentrations. Given the elevated detection limits in background samples, conclusions based on a qualitative evaluation cannot be drawn.

4.5 Subsurface Soil – Exposure Area 2

Table 5 shows Exposure Area 2 subsurface soil and background soil frequencies of detection along with the two-sample hypothesis test results and graphical comparisons are presented in **Attachments 9-10**. Frequencies of detection in **Table 5** show that the following two COPCs were not detected in background, but were detected in Exposure Area 2:

- Total PCBs (aroclors) and dibenz(a,h)anthracene.

For these COPCs no evaluations were conducted.

4.5.1 Quantitative Evaluation of Subsurface Soil COPCs – Exposure Area 2

The two-sample hypothesis test results comparing site subsurface soil and background soil concentrations are presented in **Table 5** for the seven COPCs in Exposure Area 2 with adequate data to conduct quantitative comparisons:

- Aluminum, arsenic, total chromium, cobalt, iron, manganese, and vanadium.

The remaining two site subsurface soil COPCs that were measured in background samples had frequencies of detection less than 60% in site and/or background subsurface soil, and therefore, quantitative comparisons were not conducted for:

- Thallium and benzo(a)pyrene.

Based on the Shapiro-Wilk test, the distributions of site subsurface soil datasets are not normal. For background soil datasets four COPCs were normally distributed (aluminum, total chromium, iron, and vanadium). The remaining three COPCs were not normally distributed (arsenic, cobalt, and manganese) in background.

Datasets that included 100% frequency of detection (with not normal distributions) or where detection limits (> 60% detect) were equal were evaluated using the WMW test. All seven COPCs were evaluated using the WMW test. The results of the WMW tests are as follows:

- Null hypothesis not rejected: site concentrations of aluminum, iron, and vanadium are less than or equal to background concentrations.
- Null hypothesis rejected: site concentrations of arsenic, total chromium, cobalt, and manganese are greater than background concentrations.

Attachment 9 includes graphs for the COPCs which were evaluated with two-sample hypothesis tests. The graphs of COPCs which were evaluated with two-sample hypothesis tests support the test results.

4.5.2 Qualitative Evaluation of Subsurface Soil COPCs – Exposure Area 2

Qualitative evaluations (i.e., graphical comparisons) were conducted for those COPCs in Exposure Area 2 with low frequency of detection. **Attachment 10** presents graphs for the following COPCs in Exposure Area 2 that had <60% frequency of detection:

- Thallium and benzo(a)pyrene.

The cumulative percentage plots of thallium show that background concentrations (red dots) were not detected except in one sample, while site concentrations (blue dots) were detected in all but one sample. The cumulative percentage plots also show that the detection limits of non-detected background concentrations overlap detected site concentrations.

The cumulative percentage plots of benzo(a)pyrene show low frequencies of detection in site and background concentrations. The cumulative percentage plots also show that detection limits are higher in background concentrations than site concentrations.

4.6 Sediment

The background graphical comparisons for sediment are presented in **Attachment 11.** Combined stacked dots (presenting background concentrations) and boxplot (presenting site concentrations) graphs were prepared for inorganic COPCs, including arsenic, barium, beryllium, total chromium, cobalt, copper, iron, manganese, mercury, nickel, selenium, silver, and zinc, and organic COPCs including total PAHs, benzo(a)anthracene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene. A graphical comparison for benzo(a)pyrene was not conducted given that background concentrations were not detected.

Inorganic COPCs were detected in all background samples with the exception of mercury and silver, which were detected in two out of the three samples. Maximum concentrations of arsenic, barium, beryllium, chromium, cobalt, iron, mercury, nickel, and selenium in background sediment samples fall in the same range as the 75^{th} to 90^{th} percentile of site sediment concentrations. Maximum concentrations of copper, manganese, and zinc in background sediment fall in the same range as the median of site sediment concentrations. Maximum background concentrations of silver fall between the 10^{th} and 25^{th} percentiles of site sediment concentrations.

For organic COPCs, only total PAHs was detected in all three background sediment samples; benzo(a)anthracene was detected in two out of three samples and dibenzo(a,h)anthracene and indeno(1,2,3-cd)pyrene were detected in one out of three samples. Maximum concentrations of total PAHs, benzo(a)anthracene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene in background sediment samples fall within the same range as the 10^{th} to 25^{th} percentile of site sediment concentrations.

4.7 Surface Water

The background graphical comparisons for surface water are presented in **Attachment 12.** Combined stacked dots (presenting background concentrations) and boxplot (presenting site concentrations) graphs were prepared for dissolved barium, total barium, dissolved iron, total iron, dissolved manganese, total manganese, total aluminum, total cadmium, and total selenium. Metals were detected in all three background surface water samples except selenium and silver, which were detected in one out of the three background samples. Total silver was only detected in three of 14 site surface water samples and therefore, a boxplot could not be used to summarize site concentrations. As a result both site and background concentrations for total silver were presented using stacked dots. Total mercury was identified as a COPC for the ecological risk assessment; however, a graph comparing site and background concentrations was not prepared because it was not detected in site surface water samples.

All concentrations of total aluminum, total barium, total iron, total manganese, and total selenium in background surface water samples fall above the range of site surface water concentrations. Maximum concentrations of total cadmium and total silver in background surface water samples fall

above the range of site surface water concentrations. Maximum concentrations of dissolved barium, dissolved iron, and dissolved manganese in background surface water fall in the same range as the 75th to 90th percentile, 90th percentile, and 50th to 75th percentile, respectively, of site surface water concentrations.

5.0 CONCLUSIONS

Several COPCs in surface soil, subsurface soil, sediment, and surface water were evaluated for consistency with background conditions. The results of the quantitative and qualitative comparisons of site and background datasets are provided below.

Surface Soil

The results of the evaluation were as follows for surface soil in Exposure Area 1:

Surface Soil – Exposure Area 1 COPC	**Quantitative Comparison Result**	**Qualitative Comparison Result**
Aluminum	Site ≤ Background	Site ≤ Background
Arsenic	Site ≤ Background	Site ≤ Background
Total Chromium	Site ≤ Background	Site ≤ Background
Cobalt	Site > Background	Site > Background
Iron	Site ≤ Background	Site ≤ Background
Manganese	Site > Background	Site > Background
Thallium	-	Conclusions Cannot Be Drawn
Vanadium	Site ≤ Background	Site ≤ Background
Benzo(a)pyrene	-	Higher Detection Limits in Background Data

The results of the evaluation were as follows for surface soil in Exposure Area 2:

Surface Soil – Exposure Area 2 COPC	**Quantitative Comparison Result**	**Qualitative Comparison Result**
Aluminum	Site ≤ Background	Site ≤ Background
Arsenic	Site ≤ Background	Site ≤ Background

Total Chromium	Site > Background	Site > Background
Cobalt	Site > Background	Site > Background
Iron	Site ≤ Background	Site ≤ Background
Manganese	Site > Background	Site > Background
Thallium	-	Conclusions Cannot Be Drawn
Vanadium	Site ≤ Background	Site ≤ Background
Benzo(a)anthracene	-	Site > Background
Benzo(a)pyrene	-	Higher Detection Limits in Background Data
Benzo(a)fluoranthene	-	Higher Detection Limits in Background Data
Benzo(k)fluoranthene	-	Higher Detection Limits in Site Data
Indeno (1,2,3-cd)pyrene	-	Higher Detection Limits in Background Data

The results of the evaluation were as follows for site-wide surface soil:

Surface Soil – Site-Wide COPC	**Quantitative Comparison Result**	**Qualitative Comparison Result**
Cadmium	Site ≤ Background	Site ≤ Background
Total Chromium	Site > Background	Site > Background
Cobalt	Site > Background	Site > Background
Lead	Site ≤ Background	Site ≤ Background
Manganese	Site > Background	Site > Background
Mercury	Site ≤ Background	Site ≤ Background
Selenium	Site ≤ Background	Site ≤ Background
Vanadium	Site ≤ Background	Site ≤ Background
Zinc	Site > Background	Site > Background
4,4-DDT	-	Higher Detection Limits in Site Data

Total HMW PAHs	Site > Background	Site > Background
Total LMW PAHs	-	Higher Detection Limits in Site Data

Subsurface Soil

The results of the evaluation for subsurface soil in Exposure Area 1 were as follows:

Subsurface Soil – Exposure Area 1 COPC	**Quantitative Comparison Result**	**Qualitative Comparison Result**
Aluminum	Site ≤ Background	Site ≤ Background
Arsenic	Site ≤ Background	Site ≤ Background
Total Chromium	Site > Background	Site > Background
Cobalt	Site > Background	Site > Background
Iron	Site ≤ Background	Site ≤ Background
Manganese	Site > Background	Site > Background
Thallium	-	Conclusions Cannot Be Drawn
Vanadium	Site ≤ Background	Site ≤ Background

The results of the evaluation for subsurface soil in Exposure Area 2 were as follows:

Subsurface Soil – Exposure Area 2 COPC	**Quantitative Comparison Result**	**Qualitative Comparison Result**
Aluminum	Site ≤ Background	Site ≤ Background
Arsenic	Site > Background	Site > Background
Total Chromium	Site > Background	Site > Background
Cobalt	Site > Background	Site > Background
Iron	Site ≤ Background	Site ≤ Background
Manganese	Site > Background	Site > Background

Thallium	-	Site and Background Overlap
Vanadium	Site $\leq$ Background	Site $\leq$ Background
Benzo(a)pyrene	-	Higher Detection Limits in Background Data

Sediment

The combined stacked dot/boxplots comparing background and site concentrations show that maximum concentrations in background fall near the 90th, 75th, or 50th percentile of site concentrations for inorganic COPCs except silver.

- The maximum concentration of silver in background sediment is less than the 25th percentile of site sediment concentrations.

Therefore, for all inorganic COPCs except silver, site sediment concentrations are less than or consistent with background.

Concentrations of total PAHs, benzo(a)anthracene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene in background sediment samples are less than the 25th percentile of site sediment concentrations. Therefore, site sediment concentrations of these COPCs are greater than background concentrations.

Surface Water

The combined stacked dot/boxplots comparing background and site surface water concentrations, respectively, show that all maximum concentrations in background fall above site concentrations for all COPCs except dissolved barium, dissolved iron, and dissolved manganese, which fall in the same range as the 75th to 90th percentile, 90th percentile, and 50th to 75th percentile, respectively, of site surface water concentrations. Therefore, site surface water concentrations of all COPCs are less than or consistent with background.

Notes:
The calculation of the summary statistics is based on detected concentrations only.
Summary statistics exclude arsenic and lead from sample A-11, lead from sample A-11 offset, and PAHs from sample A-4.
Vinyl chloride is a COPC in subsurface soil in exposure area 1 based on the human health risk assessment, however, this COPC was not analyzed in the background study.
1,1-biphenyl, acetone, bis(2-ethylhexyl)phthalate, carbazole, carbon disulfide, dibenzofuran, dichlorodifluoromethane, and methyl acetate are COPCs in surface soil based on the ecological risk assessment, however, these COPCs were not analyzed in the background study.

COPC - Chemical of Potential Concern.
FOD - Frequency of Detection.
HMW - High Molecular Weight.
LMW - Low Molecular Weight.
PAHs - Polycyclic Aromatic Hydrocarbons.

Notes:
The calculation of the summary statistics is based on detected concentrations only.
Summary statistics for all COPCs except copper are based on samples SD-R04, SD-R05, and SD-R06.
Summary statistics for copper are based on samples SD-R05 and SD-R06.
Thallium, total PCBs, 4,4-DDD, 4,4-DDE, 4,4-DDT, dieldrin, endosulfan sulfate, endrin aldehyde, endrin ketone, 1,4-dioxane, 2,4-dinitrotoluene, bis(2-ethylhexyl)phthalate, carbazole, dibenzofuran, acetone, cis-1,2-dicholorethene, methyl cyclohexane, and toluene are COPCs in sediment based on the ecological risk assessment, however, these COPCs were not analyzed in the background freshwater sediment samples.
Total PCBs and benzo(b)fluoranthene are COPCs in sediment based on the human health risk assessment, however, these COPCs were not analyzed in the background freshwater sediment samples.

COPC - Chemical of Potential Concern.
FOD - Frequency of Detection.
PAH - Polycyclic Aromatic Hydrocarbons.

Notes:
(a) Two-sample hypothesis tests were only run on concentrations if both background and site datasets had frequencies of detect greater than 60%.
(b) The distribution of the Site and Background datasets were determined using Goodness of Fit Statistics (significance level 0.05) in ProUCL 5.1.
(c) A two-sample hypothesis test was conducted. An unequal variance t-test was used when both Site and Background datasets were all detected samples with normal distributions. If either datasets were not normally distributed or both datasets were normally distributed, however, not all samples had detected concentrations, then the WMW test or the Gehan test was used depending on if detection limits were equal for all non-detected samples (WMW) or if they were not equal (Gehan).
The null hypothesis is Mean/Median of Site Surface Soil <= Mean/Median of Background Soil. The alternative hypothesis is Mean/Median of Site Surface Soil > Mean/Median of Background Soil.
If the p-value of the two-sample hypothesis test is < alpha (0.05), then the null hypothesis is rejected.

COPC - Chemical of Potential Concern.
FOD - Frequency of Detection.
HMW - High Molecular Weight.
LMW - Low Molecular Weight.
PAH - Polycyclic Aromatic Hydrocarbon.
WMW - Wilcoxon-Mann-Whitney test.

1.0 INTRODUCTION

This appendix presents a human health risk assessment (HHRA) conducted for the Fire Training Area (FTA) (site) located at the Naval Computer and Telecommunications Area Master Station Atlantic Detachment (NCTAMS LANT Det) in Cutler, Maine (Cutler) (**Figure 1**). This HHRA addresses the potential for human health risks associated with historical site activities at the FTA.

The FTA (Site 1) consists of a former borrow pit that was used by the Navy for firefighting training exercises from the early 1960s to the 1980s and a drum disposal area (DDA) (Site 5) located on the southern edge of the FTA. Since the DDA was physically located within the boundaries of the FTA, the DDA and former borrow pit were combined into a single site in 2012 and all environmental issues were addressed as Site 1. The chemicals associated with these activities, and therefore potentially present at the site, include volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), petroleum hydrocarbons, poly- and perfluoroalkyl substances (PFASs), and metals. The site history and a site description are presented in detail in the Remedial Investigation (RI) main report text. The FTA encompasses 10.27 acres, of which 3.26 acres in the central portion of the site is wetlands (including the Sand Wedge restored wetland [0.44 acres] and the enhanced wetlands [2.84 acres]).

1.1 Objectives

The primary objective of the HHRA is to evaluate whether exposure to chemicals of potential concern (COPCs) attributable to past operations at the FTA may pose a risk to human health above United States (U.S.) Environmental Protection Agency (USEPA) or Maine Department of Environmental Protection (MEDEP) target levels. The evaluation focuses on quantitative estimation of current and potential future risks and hazards to current and potential future human receptors that may be exposed to site-related chemicals in soil, groundwater, air, sediment, and surface water at the FTA.

1.2 HHRA Approach

The HHRA was performed in accordance with Navy, USEPA, MEDEP, and Maine Center for Disease Control and Prevention (CDC) risk assessment guidance and other related guidance. Guidance documentation includes, but is not limited to, the following:

- *Navy Policy for Conducting Human Health Risk Assessments Under the Environmental Restoration Program* (DON 2001)
- *Navy Policy on the Use of Background Chemical Levels* (DON 2004)
- *Department of the Navy Environmental Restoration Program Manual* (DON 2006)
- *U.S. Navy Human Health Risk Assessment Guidance* (DON 2008)

- *Risk Assessment Guidance for Superfund, Volume I, Human Health Evaluation Manual* (Parts A, B, D, E, and F) (USEPA 1989; 1991; 2001; 2004a; 2009)
- *Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites* (USEPA 2002a)
- *Human Health Toxicity Values in Superfund Risk Assessments* (USEPA 2003)
- *Exposure Factors Handbook* (USEPA 2011)
- *Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors* (USEPA 2014a)
- *Guidance For Human Health Risk Assessments For Hazardous Substance Sites in Maine* (MEDEP/CDC 2011)
- *Standard Default Exposure Assumptions for Maine Risk Assessments (Table 1)* (MEDEP/CDC 2013)

The HHRA approach used in this document generally follows the approach used for evaluation of the Site 4/Very Low Frequency (VLF) Peninsula risk assessment (Resolution 2016a) and the Salvage Yard Area (SYA) risk assessment (Resolution 2016b) to provide consistency in the HHRA approach between multiple sites within the NCTAMS LANT Det Cutler.

Pursuant to the *Navy Policy for Conducting Human Health Risk Assessments Under the Environmental Restoration Program* (DON 2001), the determination of human health risk at a site is clearly prescribed to ensure sufficient resources are allocated for the protection of human health. The Navy Policy for conducting HHRAs identifies a three-tiered approach that may be implemented in its entirety depending on the level and magnitude of incremental risk or hazard that is determined in prior tiers. The following sections describe the tiers followed for this HHRA.

1.2.1 Tier IA – Human Health Risk-Based Screening Evaluation

The Tier IA human health risk-based screening evaluation includes the following:

- Identify and summarize relevant datasets.
- Refine the conceptual site model (CSM) for potentially complete exposure pathways for both current and future land uses.
- Identify COPCs for further quantitative evaluation in the site-specific risk assessment (Tier II).

The Tier IB, Site-Specific Risk-Based Screening Evaluation, is an optional tier that allows for development of and comparison to site-specific risk-based screening levels. This tier of evaluation was not conducted for this HHRA.

1.2.2 Tier II – Baseline Human Health Risk Assessment

The Tier II baseline HHRA includes the following:

- *Data Evaluation and Reduction:* Conducted in Tier IA.
- *Exposure Assessment:* Includes reevaluation of the CSM, if appropriate and necessary, and identification of potential receptors, pathways, and intake factors for both current and future land uses.
- *Toxicity Assessment:* Includes the hazard identification and dose-response assessment processes in which it is determined whether exposure to a chemical can cause an adverse health effect in humans; and identification of toxicity values and chemical-specific values for carcinogenic and noncarcinogenic COPCs.
- *Risk Characterization:* Integrates the toxicity and exposure assessments to estimate the potential risk associated with COPCs at the site and identifies risk drivers/risk-based chemicals of concern (COCs) above target risk/hazard levels.
- *Uncertainty Analysis:* Discusses the uncertainty associated with all aspects of the HHRA or limitations that may have a significant impact on the outcome of the HHRA due to an underestimation or overestimation of risk.

Section 2.0 presents the data evaluation; **Section 3.0** presents the Tier IA human health risk-based screening evaluation; and **Section 4.0** presents the Tier II baseline HHRA. Tables and figures are presented at the end of the text. Tables are numbered based on the Risk Assessment Guidance for Superfund (RAGS) Part D (USEPA 2001) numbering system, as noted in the following table. Informational tables embedded within the text of the HHRA are not numbered.

Table #	RAGS Part D Table Title	Report Location
Table 1	Selection of Exposure Pathways (HHRA)	Tables section
Table 2	Occurrence, Distribution, and Selection of Chemicals of Potential Concern	Tables section
Table 3	Exposure Point Concentration Selection	Tables section
Table 4	Values Used for Daily Intake Calculations	Tables section
Table 5	Non-Cancer Toxicity Data	Tables section
Table 6	Cancer Toxicity Data	Tables section
Table 7	Calculation of Chemical Cancer Risks and Non-Cancer Hazards	Attachment E
Table 9	Summary of Receptor Risks and Hazards for COPCs	Attachment F
Table 10	Risk Summary	Tables section

Note: RAGS Part D Table 8 (Calculation of Radiation Cancer Risks) is not applicable to this HHRA.

This page intentionally left blank.

2.0 DATA EVALUATION

Section 2.0 summarizes the available environmental data for each media quantitatively evaluated in the HHRA. Environmental data used in this HHRA include soil, groundwater, surface water, and sediment collected on behalf of the Navy. Soil data included in the HHRA were collected between 2002 and 2014, and surface water and sediment data included in the HHRA were collected between 2012 and 2014. Groundwater data from permanent monitoring wells collected between 2012 and 2016 were included in the HHRA.

Sections 1.0 and 2.0 of the RI report provides detailed discussions of the sampling events performed as part of the site investigations conducted at the FTA. Section 4.0 of the RI report discusses the nature and extent of the primary chemicals detected in site media.

2.1 Data Used in the HHRA and Identification of Exposure Areas

The following sections summarize the environmental data for each of the media quantitatively evaluated in the HHRA. **Attachment A** includes tables summarizing the samples used in the HHRA. **Attachment A** also presents individual analytical sample results. **Figures 2** and **3** identify the surface soil, subsurface soil, groundwater, sediment, and surface water sampling locations.

2.1.1 Soil

Soil samples were collected during multiple sampling events conducted between 2002 and 2016 from various depth intervals between the ground surface and 10 feet (ft) below ground surface (bgs). Soil samples were analyzed for inorganics, PCBs, pesticides, semivolatile organic compounds (SVOCs), VOCs, and total petroleum hydrocarbons (TPH). Surface soil samples collected in November 2016 were analyzed for both total and hexavalent chromium. The sample locations for chromium analysis were selected from undisturbed areas with the highest concentrations of chromium in previous sampling. Samples locations were selected in conjunction with MEDEP.

For the purposes of the HHRA, and for consistency with the VLF Peninsula/SYA HHRAs (Resolution 2016a,b) surface soil is defined as soil collected within the 0–2 ft depth interval and subsurface soil is defined as soil collected within the depth interval ranging from > 2 to 15 ft bgs. One soil sample (FTA-SS-23) was collected from 1–3 ft bgs, which overlaps both the surface and subsurface soil depth intervals. The soil sample collected from 1–3 ft bgs was treated as subsurface soil in the HHRA because the 1–3 ft bgs interval does not include the most surficial soils. The sample was analyzed for VOCs only and, consistent with other subsurface soil samples, contains low or non-detect concentrations of VOCs.

Samples identified as removed during excavations were not included in the HHRA. Potential impacts due to petroleum products are assessed using the relevant VOCs (i.e., benzene, toluene, ethylbenzene, xylene) and PAH data. Therefore, soil results for TPH were not evaluated in the HHRA.

Soil exposure areas (i.e., the area of the FTA not including the wetlands) were defined based on a review of analytical data and the spatial distribution of key COPCs, primarily Total PCBs (referred to as Total Aroclors in the **Attachment A** data tables) and secondarily PAHs. Figure 4-3 of the RI report spatially depicts concentrations of PCB Aroclor-1260. Significant remediation was conducted on the northern portion of the FTA, historically used for firefighting training. Chemical concentrations are generally lower than in the more southern portion of the site, historically used for drum disposal. Within the northern portion, metals concentrations appear similar to background, and concentrations of PCBs, PAHs, and other organics are low to non-detect. There are no localized areas within the northern portion with higher chemical concentrations. Therefore, the more northern area is treated as one exposure area, referred to as Soil Exposure Area 1, encompassing 5.56 acres, and includes all the soil within the FTA boundaries outside of Soil Exposure Area 2, described as follows.

While concentrations of metals in the southern area are similar to those in the northern area, concentrations of PCBs, PAHs, and other organics in the southern area are higher and more widespread. No discernable pattern was identified for elevated PCB concentrations within the southern area, with three surface soil samples exhibiting relatively high concentrations of Total PCBs (PCBAREA1-011, 013, and 014 at 240 milligrams per kilogram [mg/kg], 610 mg/kg, and 140 mg/kg, respectively). However, the samples surrounding these locations showed much lower PCB concentrations. Therefore, these locations were not treated separately and the southern area was treated as one exposure area, referred to as Soil Exposure Area 2, and is 1.45 acres in size. Note that a small portion of land below Soil Exposure Area 2 is included in Soil Exposure Area 1, which includes location FTA-SB-208. The soil exposure areas do not include the wetlands, which are treated as one exposure area for sediment and surface water.

Figure 2 depicts the locations of Soil Exposure Area 1, Soil Exposure Area 2, and the wetlands, as well as sample locations for soil, sediment, surface water, and groundwater. Due to the large number of samples located in Soil Exposure Area 2, **Figure 3** provides a magnification of Soil Exposure Area 2. A list of soil samples and a summary of the analytical soil data evaluated in the HHRA are presented in **Attachment A**, Tables A-1a and A-1b, respectively. The list of soil samples also indicates whether the sample is located in Soil Exposure Area 1 or Soil Exposure Area 2.

2.1.2 Groundwater

Groundwater samples were collected during multiple sampling events conducted between 1999 and 2016. Groundwater samples were analyzed for total and dissolved phase inorganics, PCBs, pesticides, SVOCs, VOCs, TPH, and PFASs (perfluorooctanesulfonic acid [PFOS] and perfluorooctanoic acid [PFOA]). Note that the acid name for PFOS is used for consistency with the analytical method. USEPA's health advisory (USEPA 2016e) uses the anion name, perfluorooctane sulfonate. For the purposes of this report, the acid and anion forms of the name refer to the same

substance. Potential impacts due to petroleum products are assessed using the relevant VOCs (i.e., benzene, toluene, ethylbenzene, xylene) and PAH data. Therefore, groundwater results for TPH were not evaluated in the HHRA.

The HHRA utilizes the total (unfiltered) groundwater data for oral exposure pathways, consistent with the recommendation in USEPA (2004a). As discussed in **Section 4.7.5.3**, the use of unfiltered data for the dermal contact pathway is conservative.

USEPA (2014b) recommends that where no seasonal trends are identified, the latest two rounds of data from each well, generally from the past year, be used to develop exposure point concentrations (EPCs) for groundwater. The hydrograph of groundwater elevation data from 2012 to 2015 (Figure 3-4 of the RI report) reveals no discernable patterns in seasonal groundwater flow. Therefore, the use of multiple rounds of data from the same well is appropriate for this HHRA.

The guidance also recommends a minimum of 10 data points per chemical. The latest two rounds of sampling include June 2014 and June 2015 (with one additional round included at FTA-MW-206 in September 2013 for PCBs, pesticides, SVOCs, and VOCs, and one additional round included at FTA-MW-208 in November 2016 for total and hexavalent chromium only). However, because the 2014 and 2015 rounds had slightly varying analyte lists for SVOCs and VOCs, the November 2012 round was included to ensure adequate data points per chemical and well. Groundwater data collected before 2012 were not used in the HHRA, as the more recent data are more reflective of current conditions.

As indicated in USEPA (2014b), groundwater data from monitoring wells are preferred over data collected from soil borings and/or temporary well locations, as results for temporary wells may not be reproducible. Permanent groundwater wells located in the FTA are as follows:

- FTA-MW-1
- FTA-MW-5
- FTA-MW-9
- FTA-MW-10
- FTA-MW-11
- FTA-MW-12
- FTA-MW-14
- FTA-MW-203
- FTA-MW-206

- FTA-MW-208
- FTA-MW-210
- FTA-MW-218
- DP-35

Based on September 2015 monitoring well gauging data, the direction of shallow groundwater flow, in the surficial materials, is generally to the north toward the wetland area. FTA-MW-203, FTA-MW-208, and FTA-MW-218 are located hydraulically upgradient from the wetland area and distant from any site-related activities. With the exception of a very low level detection of PFOA in FTA-MW-218, only inorganics were detected in these wells, suggesting the wells are not site impacted and are more consistent with upgradient conditions. The PFOA detection is an estimated concentration at or near the detection limit (DL) and below the screening level, and likely represents a sampling artifact rather than a site-related condition. Therefore, these three upgradient wells were not included in the HHRA.

USEPA guidance indicates that groundwater EPCs should be derived based on monitoring wells within the center or core of the plume (USEPA 2014b). Based on a review of the analytical data, there does not appear to be a dominant plume area. While some wells exhibit higher concentrations of certain chemicals, no discernable pattern was identified. Therefore, with the exception of the three upgradient wells, the permanent wells listed previously were included in the HHRA.

A list of groundwater samples and a summary of the analytical groundwater data evaluated in the HHRA are presented in **Attachment A**, Tables A-2a and A-2b, respectively.

2.1.3 Wetlands

The total acreage of the Sand Wedge restored wetland (0.44 acres) and the enhanced wetland (2.84 acres) within the FTA is 3.26 acres. Both the restored wetland and enhanced wetland were evaluated as one exposure area for both surface water and sediment, referred to in the remainder of this report as the wetland area.

2.1.3.1 Wetland Surface Water

Surface water samples were collected from the wetland area in November 2012 and June 2014. Surface water samples were analyzed for total and dissolved phase inorganics, PCBs, SVOCs, VOCs, and TPH. The HHRA utilizes only the total (unfiltered) inorganic surface water data. As discussed in **Section 4.7.5.3**, the use of unfiltered data for the dermal contact pathway is conservative. Potential impacts due to petroleum products are assessed using the relevant VOCs (i.e., benzene, toluene, ethylbenzene, xylene) and PAH data. Therefore, surface water results for TPH were not evaluated in the HHRA. A list of surface water samples and a summary of the analytical surface

water data evaluated in the HHRA are presented in **Attachment A**, Tables A-3a and A-3b, respectively.

2.1.3.2 Wetland Sediment

Sediment samples were collected from the wetland area in November 2012, June 2014, and November 2016 (one sample) from the ground surface to 0.5 ft bgs. The 2012 and 2014 sediment samples were analyzed for inorganics, PCBs, pesticides, SVOCs, VOCs, and TPH. The sediment sample collected in November 2016 (FTA-SED-07) was analyzed for total and hexavalent chromium only. Location FTA-SED-07 was selected for chromium speciation because it had the highest chromium concentration previously detected. Potential impacts due to petroleum products are assessed using the relevant VOCs (i.e., benzene, toluene, ethylbenzene, xylene) and PAH data. Therefore, sediment results for TPH were not evaluated in the HHRA. A list of sediment samples and a summary of the analytical sediment data evaluated in the HHRA are presented in **Attachment A**, Tables A-4a and A-4b, respectively.

2.2 Background

Background data are available for soils, sediments, and surface water. The *Background Study for Remedial Investigations for Installation Restoration Sites at NCTAMS LANT Det in Cutler, Maine* (Battelle 2005) described the collection of background surface soil samples (0–1 ft bgs). Samples collected from 15 locations in each of the two primary soil types (glacial till and glacio-marine sediments) were considered applicable to the FTA. Three freshwater sediment reference samples collected as part of the SYA RI effort in 2009 are considered to be background samples for the freshwater sediments of the FTA. The data associated with the soil, sediment, and surface water background samples are included in Appendix B of the RI report.

The background evaluation consisted of statistical comparisons of site and background datasets for media/chemicals for which a sufficient background dataset was available. Where requirements for conducting a statistical evaluation were not met, a qualitative/graphical comparison was performed. Appendix C of the RI report includes the background evaluation considered in the HHRA. The conclusions of the background evaluation for COPCs are summarized as follows.

2.2.1 Soil

The statistical analyses and graphical displays indicate that surface soil and subsurface soil concentrations of the following COPCs are less than or similar to concentrations in the background soil dataset as follows:

COPC	Soil Exposure Area 1		Soil Exposure Area 2	
	Surface Soil	Subsurface Soil	Surface Soil	Subsurface Soil
Aluminum	X	X	X	X
Arsenic	X	X	X	
Iron	X	X	X	X
Vanadium	X	X	X	X

Note:
X = Site concentrations less than or similar to background concentrations (see Appendix C of the RI report).

2.2.2 Sediment and Surface Water

Due to the small size of the background surface water and sediment data sets (n=3 or n=2), a robust statistical population comparison against the site data could not be conducted. Appendix C of the RI report includes a tabular summary and a graphical display of the site and background data.

Sediment

COPCs in wetland sediment include PCBs, arsenic, cobalt, iron, and several PAHs. Background data are available for the metals and benzo(a)anthracene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene. Benzo(a)pyrene was not detected in the background samples, and PCBs and benzo(b)fluoranthene were not analyzed.

The combined stacked dot/boxplots comparing background and site concentrations in Appendix C of the RI report show that maximum background concentrations fall near the 90th percentile of site concentrations for arsenic and iron, and near the 75th percentile for cobalt. Therefore, site concentrations of arsenic, cobalt, and iron and are considered to be consistent with background in sediment.

The boxplots in Appendix C of the RI report show that the maximum concentrations of benzo(a)anthracene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene in background sediment samples are less than the 25th percentile of site sediment concentrations. Therefore, site sediment concentrations of these COPCs are greater than background concentrations.

Surface Water

COPCs in wetland surface water include arsenic, manganese, thallium, and several organics. Of the COPCs, background data are available only for manganese. Background concentrations of total manganese range from 4,310 micrograms per liter (µg/L) to 12,300 µg/L and are higher than site concentrations, which range from 28.3 µg/L to 1,190 µg/L (see the boxplot included in Appendix C of the RI report).

2.2.3 Background Evaluation Conclusions

The results of the background evaluation indicate that concentrations of aluminum, arsenic, iron, and vanadium in soil are consistent with background concentrations (with the exception of arsenic in Soil Exposure Area 2 subsurface soil). Concentrations of arsenic, cobalt, and iron in wetland sediment are also consistent with background concentrations. Manganese concentrations in wetland surface water are lower than background levels. While chemicals within background levels are not attributed to Navy activities, background levels have not been used for screening purposes but are considered in the Tier II HHRA if necessary following the identification of risk drivers.

2.3 Data Treatment

Analytical data were evaluated, validated, and qualified prior to use in the risk assessment. Data evaluation and validation included a comparison of the site data to corresponding blank (laboratory, field, equipment, and trip) concentration data. As described in the data validation report (Appendix B of the RI report), some results, primarily for SVOCs such as various phenols and caprolactam, were rejected during data validation. The impact of rejecting this small amount of data for chemicals that are unlikely to be site-related is minimal. Data rejected by the evaluation ("R" qualified) were not used in the HHRA. Estimated values ("J" qualified) were used in the HHRA without modification. If the value was flagged with "U" or "UJ," the result was considered a non-detect value.

For each exposure area and medium, the data were compiled into summary statistics presented in **Tables 2.1** through **2.6** and discussed in the following sections. For each chemical detected at least once within an area media, the summary statistics include frequency of detection, range of DLs, range of detected concentrations, and location of maximum detected result. The following guidance documents were used to develop the summary statistics:

- *U.S. Navy Human Health Risk Assessment Guidance* (DON 2008)
- *RAGS: Volume I – Human Health Evaluation Manual, Parts A and D* (USEPA 1989; 2001)

2.3.1 Treatment of Duplicates

For sample locations in which a duplicate sample was also collected, the duplicate sample results for each chemical/medium combination were processed for use in the calculation of summary statistics. Duplicates were resolved in accordance with MEDEP/CDC guidance (2011) as follows: (1) Where both the sample and the duplicate results are not detected, the resulting value is the average of the limits of detection; (2) where both the sample and the duplicate results are detected, the resulting value is the average of the detected results; and (3) where one of the pair is reported as not detected and the other is detected, the detected concentration is used.

2.3.2 Total PCBs

The analytical dataset includes results for PCBs reported as PCB Aroclors. PCB Aroclors consist of mixtures of PCB congeners. Each PCB Aroclor mixture (e.g., PCB Aroclor-1254) is referred to as an individual PCB Aroclor throughout this HHRA report, including the associated tables and attachments). This distinguishes the reported laboratory results for each PCB Aroclor mixture, which provides a measure of a subset of PCB congeners specific to that commercial mixture, from the Total PCB (referred to as Total Aroclors in the **Attachment A** data tables) concentration that is calculated for use in this HHRA by summing the individual PCB Aroclors that were detected in each sample. It is recognized that different PCB Aroclor mixtures may contain overlapping PCB congeners.

Detected concentrations of individual PCB Aroclors in soil, sediment, and surface water were combined to calculate a Total PCB concentration per sample for evaluation in the HHRA. PCB Aroclors were not detected in groundwater. Total PCBs were calculated using two methods to determine the range of potential PCB concentrations as follows:

- *Detects Only Method:* Total PCB concentrations were calculated per sample by summing only the detected individual PCB concentrations. For samples without any detection of individual PCBs, the maximum reporting DL within the sample was used as a non-detect value.
- *Full DL Method:* Total PCB concentrations were calculated per sample by summing the individual PCB concentration for detected results and the full reporting DL for non-detect results.

The Detects Only Method was used in the HHRA calculations presented and discussed throughout the HHRA. The uncertainty assessment (**Section 4.7**) provides a discussion of if/how the potential risk/hazard results and conclusions of the HHRA would change if the Full DL Method were used instead.

2.3.3 Chromium

Chromium is most commonly present in the environment in the trivalent state because typical conditions in the environment favor the reduction of chromium from the hexavalent to the trivalent state. The data collected prior to 2016 were analyzed for total chromium. Therefore, surface soil, sediment, and groundwater samples were collected in November 2016 and were analyzed for total and hexavalent chromium. Total chromium has never been detected in surface water at the FTA and was therefore not included in the November 2016 sampling.

Sampling locations were selected based on historical high total chromium concentrations in areas known to be undisturbed, as approved by Navy and MEDEP.

Soil and Sediment

As discussed in detail in Appendix G of the RI report, multiple lines of reasoning were used to support the weight-of-evidence conclusion that hexavalent chromium is not a site-related contaminant at the FTA. Site history, background concentrations, soil characteristics, and laboratory analysis all support the conclusion that a hexavalent chromium release has not occurred. Therefore, total chromium is evaluated in the HHRA as trivalent chromium, and not hexavalent chromium, in soil and sediment.

Groundwater

Concentrations of total chromium in the permanent wells selected for evaluation in the HHRA range from 1.4 µg/L to 7.6 µg/L. Total chromium was not detected in upgradient well FTA-MW-203, and was detected in one sample from upgradient well FTA-MW-218 at a concentration of 4 µg/L. Upgradient well FTA-MW-208 has exhibited the highest concentrations of total chromium historically (maximum of 26.6 µg/L in November 2012), and was therefore selected for inclusion in the November 2016 sampling event. The November 2016 results for FTA-MW-208 indicated that total chromium was detected at a concentration of 9.97 µg/L and hexavalent chromium was detected at a concentration of 4.8 µg/L. However, given the well's upgradient location, the results are reflective of background conditions rather than site conditions.

The evaluation included in Appendix G of the RI report concludes that hexavalent chromium is not present in soils or sediments in the FTA. Therefore, soils are not a potential source of hexavalent chromium to groundwater, and it is reasonable to conclude that hexavalent chromium is also not present in groundwater in the FTA. The detection of hexavalent chromium in an upgradient well suggests either a non-site related source or that upgradient conditions that vary from the site conditions. Therefore, total chromium is evaluated in the HHRA as trivalent chromium, and not hexavalent chromium, in groundwater.

2.3.4 Analyses via Multiple Methods

Some chemicals (e.g., PAHs) were analyzed using different methods in the same samples (e.g., SVOC and extractable petroleum hydrocarbons methods). In the Tier IA evaluation, results from each of the analytical method groups were evaluated separately for the purposes of identifying COPCs.

This page intentionally left blank.

3.0 TIER IA HUMAN HEALTH RISK-BASED SCREENING EVALUATION

Section 3.0 presents the development of the Tier IA human health risk-based screening evaluation.

3.1 Conceptual Site Model

The NCTAMS LANT Det Cutler facility, situated on the 2,300-acre Cutler Peninsula on the coast of eastern Maine (**Figure 1**), was established on June 23, 1961 as a communications facility that provides radio signal transmissions with U.S. ships and submarines operating mainly in the North Atlantic and Arctic Oceans, and the Mediterranean Sea. The FTA is located in the northern portion of the NCTAMS LANT Det. Undeveloped forested land and several freshwater wetlands surround the FTA. Removal actions were conducted in the center of the FTA between 2006 and 2009 and a wetland was developed during restoration activities. The rest of the site is mainly located in an open (cleared) area, with a forested area around the perimeter. The DDA is located on the southern edge of the FTA, immediately to the south of the removal area/created wetland and directly upgradient, based on previous determinations of groundwater flow. Previous removal actions have removed over 30 drums and drum remnants from the DDA.

Currently, the FTA is unused and undeveloped open space. While there are no physical access restrictions to the FTA, human access to the area is prohibited and is restricted to Cutler base personnel performing operation and maintenance. Currently, there is no residential or recreational use, and children are not permitted to access the FTA. Access to the peninsula is restricted by base security and can only be gained through a security checkpoint located in the northern portion of the base along Ridge Road. The entrance to the NCTAMS LANT Det Cutler is accessed via Ridge Road located approximately 1.5 miles west of Route 191 in Cutler, Maine (Tetra Tech 2010). There are currently no future redevelopment plans.

For the purposes of the HHRA, it was conservatively assumed that humans may trespass onto the site and access site soils, in addition to surface water and sediment within the wetland area via a wading exposure scenario. Standing water may be seasonally present within the wetland; however, fish suitable for human consumption are not expected to be present. Maximum water depths during the 2014 wetland sampling effort were approximately 6 inches with no standing water present at some locations, as indicated in the following table:

Location	Sample Date	Inches of Standing Water
FTA-SW-01	6/19/2014	3
FTA-SW-02	6/19/2014	3 to 4
FTA-SW-03	6/19/2014	2
FTA-SW-06	6/19/2014	2 to 3

Location	Sample Date	Inches of Standing Water
FTA-SW-07	6/19/2014	6
FTA-SW-08	6/19/2014	6

Therefore, any recreational activities involving surface water (e.g., wading) are expected to be minimal.

Under the current scenario, trespassing for recreational use is extremely unlikely given the access prohibitions in place. Under the future scenario, recreational use may also be limited due to the lack of fishing or other desirable recreational activities. There are currently no plans for opening the area to recreational activities. However, a current/future recreational user exposure scenario was evaluated in the HHRA to be protective of both a current trespasser exposure scenario and a future recreational-use exposure scenario, conservatively assuming access to the area is unrestricted in the future and becomes accessible for recreational use (e.g., hiking and camping).

Currently, there are no workers at the FTA. The FTA is not regularly maintained and there are no activities occurring in the area. Future land use of the site is likely to remain constant into the future. However, it was conservatively assumed that future receptors may include industrial workers and residents under a hypothetical scenario in which the area is redeveloped for regular commercial/industrial and/or residential use. Future outdoor industrial workers are assumed to contact soil, while future indoor industrial workers may be exposed to volatiles in groundwater via the vapor intrusion pathway. Future industrial workers are not considered to be routinely exposed to groundwater, surface water, or sediment.

While no residential development is planned for the site, hypothetical future residents are assumed to contact soil, groundwater (via ingestion of drinking water, contact while bathing/showering, and the vapor intrusion pathway), and surface water and sediment assuming they may wade into the wetland area. Although it is an unlikely future scenario, evaluation of a hypothetical future residential exposure scenario in the HHRA provides useful information for decision-making purposes (e.g., implementation of land use restrictions or remedial activities).

Finally, it was assumed that construction workers may access the site under a current/future use scenario and may access soil, groundwater, and volatiles in air within an excavation trench originating from groundwater, and surface water and sediment within the wetland area, assuming they may perform activities along the edges of the wetland. For example, a construction worker may perform excavation activities at the FTA similar to those that have occurred in the past, including soil removal and regrading.

The site CSM and potential source areas, migration pathways, and potentially exposed receptors for the site are presented in **Table 1** and illustrated on **Figure 4**.

3.2 Identification of COPCs

The Tier IA evaluation includes identification of COPCs based on a comparison of the maximum detected concentrations of the chemical substances at the site to the screening or regulatory values for each medium discussed as follows. For each medium evaluated, all available and appropriate data from each medium were used to select COPCs. Chemicals detected at concentrations above the screening or regulatory values were identified as COPCs for further review in the Tier II evaluation. Chemicals that were not detected in a particular medium or were detected at concentrations below the screening or regulatory values were eliminated from being COPCs for the associated receptor and were not evaluated further. No chemicals were eliminated due to a low frequency of detection for this evaluation.

Comparisons of maximum concentrations to screening levels discussed in **Section 3.2.1** are presented in the data summary tables for each medium (**Tables 2.1** through **2.5**). For certain analytes lacking a chemical-specific screening level (e.g., Total PCBs), a conservative surrogate chemical was selected (e.g., PCB Aroclor-1254) and its screening level was used for COPC screening. Specific instances where surrogate assignments were made are identified in footnotes in **Tables 2.1** through **2.5**. Due to slightly varying analyte lists between rounds, the frequency of detection may vary between analytes in the same group. For instance, the VOC vinyl chloride and the SVOCs 1,1-biphenyl and hexachlorocyclopentadiene were not included in the September 2015 groundwater analytical list, but were included in November 2012 and June 2014. Similar situations occurred with other media.

3.2.1 COPC Selection

Screening levels and regulatory criteria were used to select COPCs as discussed per media in the following sections.

3.2.2 Soil

Soil COPCs were selected on an exposure area basis, as described in **Section 2.1.1**. For each soil dataset (i.e., surface soil and subsurface soil), the maximum detected concentration of a chemical in soil in each exposure area was compared to the USEPA Regional Screening Level (RSL) for soil (USEPA 2016a) based on a target excess lifetime cancer risk (ELCR) of 10^{-6} and a target hazard quotient (HQ) of 0.1. The RSLs based on a target HQ of 0.1 were used to account for potential cumulative effects of multiple chemicals acting on the same target organ. Residential soil RSLs were used to select COPCs for all scenarios. While residential soil RSLs are not applicable to the industrial and construction worker scenarios, residential RSLs were conservatively used to generate a consistent COPC list for each exposure area. Chemicals with a maximum detected

concentration greater than the associated screening level were selected as COPCs for further evaluation in the HHRA. **Tables 2.1** and **2.2** present the COPC selection for Soil Exposure Area 1 and Soil Exposure Area 2, respectively.

3.2.3 Groundwater

Available groundwater data were reviewed to identify the dataset appropriate for use in the HHRA, as discussed in **Section 2.1.2**. The groundwater dataset was selected to be representative of current conditions while accounting for potential seasonal fluctuations; groundwater was evaluated as one exposure area.

The maximum detected concentration of a chemical in groundwater was compared to the USEPA Maximum Contaminant Level (MCL) (USEPA 2016b) and the USEPA tapwater RSL (USEPA 2016a) based on a target ELCR of 10^{-6} and a target HQ of 0.1 (to account for potential cumulative effects of multiple chemicals acting on the same target organ). MCLs and RSLs were used to identify COPCs for the ingestion, dermal contact, inhalation of shower air, and inhalation of trench air pathways.

The maximum detected concentration of a chemical in groundwater was also compared to the USEPA Vapor Intrusion Screening Level (VISL) for groundwater based on a target ELCR of 10^{-6} and a target HQ of 0.1 (to account for potential cumulative effects of multiple chemicals on the same target organ) (USEPA 2016f). VISLs based on a residential exposure scenario were used for selection of COPCs for both the residential and industrial inhalation of indoor air pathways, conservatively resulting in one COPC list for the vapor intrusion pathway.

For PFOA and PFOS, the groundwater screening levels are equal to the lower of the following:

- USEPA's Lifetime Drinking Water Health Advisory for PFOA and PFOS of 0.07 µg/L as individual constituents, and the combined PFOA and PFOS concentration (USEPA 2016d,e) not to exceed 0.07 µg/L.
- USEPA tap water RSLs calculated using the RSL Calculator (USEPA 2016c) based on a target HQ of 0.1 (to account for potential cumulative effects of multiple chemicals acting on the same target organ). Default exposure assumptions for tapwater RSLs provided by USEPA in the calculator were used, as well as the dose-response values provided in the calculator as of 3/3/17, which include:
  - A reference dose (RfD) of 2×10^{-5} milligram of chemical per kilogram of body weight per day [mg/kg-day] developed for both PFOA and PFOS in the Drinking Water Health Advisory documents (USEPA 2016d,e).
  - A cancer slope factor (CSF) of 0.07 $(mg/kg\text{-}day)^{-1}$ for PFOA developed in the Health Effects Support Document for PFOA (USEPA 2016k).

Table 2.3 presents the COPC selection for groundwater.

3.2.4 Surface Water

The wetlands were treated as one exposure area. The maximum detected concentration of a chemical in wetland surface water was compared to the following:

- USEPA *National Recommended Water Quality Criteria for Priority Pollutants*. Value for Human Health for the consumption of water and organisms (USEPA 2016g).
- MEDEP Surface Water Quality Criteria for human health consumption of water and organisms (MEDEP/CDC 2012).
- Risk-based screening levels for surface water were calculated using the USEPA RSL Calculator (USEPA 2016c) for a recreational adult/child scenario, based on a target ELCR of 10^{-6} and a target HQ of 0.1 (to account for potential cumulative effects of multiple chemicals acting on the same target organ). The following exposure assumptions were utilized for calculation of surface water screening levels based on USEPA's default exposure assumptions (USEPA 2014a) and MEDEP's default recommended exposure assumptions for a recreational exposure scenario (MEDEP/CDC 2013):
  - Exposure frequency (days/year) = 78
  - Exposure duration (years) = Adult – 20, Child – 6
  - Exposure time (hours/day) = 2.6
  - Body weight (kilogram [kg]) = Adult – 80, Child – 15
  - Skin surface area (square centimeter [cm^2] per day) = Adult – 6,032, Child – 2,373
  - Ingestion rate (liter per hour) = Adult – 0.01, Child – 0.05 (recommended surface water intake rate while wading [USEPA 2014c])

Chemicals detected at a maximum concentration in surface water greater than any of the above screening levels were selected as surface water COPCs for further evaluation in the HHRA. **Table 2.4** presents the COPC selection for surface water.

3.2.5 Sediment

The wetlands were treated as one exposure area. Published human health screening levels for sediment are not available. Risk-based screening levels for sediment were calculated using the USEPA RSL Calculator (USEPA 2016c) for a recreational adult/child scenario, based on a target ELCR of 10^{-6} and a target HQ of 0.1 (to account for potential cumulative effects of multiple chemicals acting on the same target organ). The following exposure assumptions were utilized for calculation of sediment screening levels based on USEPA's default exposure assumptions

(USEPA 2014a) and MEDEP's default recommended exposure assumptions for a recreational exposure scenario (MEDEP/CDC 2013):

- Exposure frequency (days/year) = 78
- Exposure duration (years) = Adult – 20, Child – 6
- Exposure time (hour/event) = 0 (used for inhalation pathway only, which is not applicable to sediment exposure)
- Body weight (kg) = Adult – 80, Child – 15
- Skin surface area (cm^2 per day) = Adult – 6,032, Child – 2,373
- Ingestion rate (milligram per day [mg/day]) = Adult – 100, Child – 200

Chemicals with a maximum detected concentration in sediment greater than the screening levels were selected as sediment COPCs for further evaluation in the HHRA. **Table 2.5** presents the COPC selection for sediment.

3.3 COPC Selection Results

Table 2.6 presents the summaries of COPCs by media. COPCs in site media are further evaluated in the Tier II HHRA as discussed in **Section 4.0**.

4.0 TIER II BASELINE HUMAN HEALTH RISK ASSESSMENT

Section 4.0 presents the development of the Tier II baseline HHRA.

4.1 Identification of Exposure Areas

For the receptors and exposure pathways identified in **Table 1**, illustrated on **Figure 4**, and detailed in **Section 4.3**, the Tier II HHRA quantitatively evaluated potential exposure to site media as discussed in the following sections.

4.1.1 Soil

Soil COPCs were selected on an exposure area basis, as discussed in **Section 2.1.1** and summarized in **Table 2.6**. Soil Exposure Area 2 consists of 1.45 acres within the southern portion of the site, characterized by higher concentrations of Total PCBs. Soil Exposure Area 1 consists of the remainder of the FTA with the exception of the wetland area (3.26 acres). Soil Exposure Area 1 is characterized by lower PCB concentrations and is 5.56 acres in size. Within each soil exposure area, concentrations of COPCs generally do not follow a discernable pattern. While concentrations of Total PCBs at two locations in Soil Exposure Area 2 (DDA-NW-6C and DDA-SW-3N) are elevated, these two locations are spatially separated and surrounding locations exhibit lower concentrations. Therefore, no further sub-areas were defined. **Figure 2** presents the exposure areas; Soil Exposure Area 2 is represented outlined and shaded in red, the wetland area is shaded in green, and the remainder of the site represents Soil Exposure Area 1, shaded in light yellow. **Attachment A**, Table A-1b identifies the soil sample locations within each soil exposure area. All receptors were evaluated separately for exposure to surface and subsurface soil within each of the individual exposure areas.

Under a hypothetical future use exposure scenario, the site could be developed for residential use and the site could hypothetically be divided into separate residential lots. The area of a typical residential lot is considered to be a minimum of 0.5 acre, especially given the rural nature of Cutler. Because the COPC concentrations within each soil exposure area are relatively consistent, exposure is expected to be similar regardless of how the areas could be subdivided in the future.

4.1.2 Groundwater

Exposure to groundwater COPCs presented in **Table 2.6** was evaluated on a site-wide basis in the Tier II HHRA. Under a hypothetical future use scenario, it is assumed that a private potable well may be installed for residential use anywhere on site. Similarly, it is assumed that under a hypothetical future use scenario, a residential or commercial/industrial building may be constructed anywhere on site, in which volatiles in groundwater may potentially migrate to overlying indoor air.

In addition, it is assumed that construction/excavation-type activities may be performed anywhere on the site. Based on September 2015 water level data from 26 site monitoring wells, the depth to groundwater ranges from less than 0.5 ft to approximately 13 ft bgs. Given the relatively shallow

groundwater present, it was assumed that a construction worker may contact groundwater during construction/excavation-type activities.

As discussed in **Section 2.1.2**, and consistent with USEPA guidance (2014b), groundwater exposure is evaluated based on monitoring wells within the core or center of the plume area. Since a discernable pattern was not identified, groundwater EPCs were calculated based on the permanent monitoring wells located in the FTA, with the exception of upgradient wells FTA-MW-203, FTA-MW-208, and FTA-MW-218. The wells included in the EPC derivation are as follows:

- FTA-MW-1
- FTA-MW-5
- FTA-MW-9
- FTA-MW-10
- FTA-MW-11
- FTA-MW-12
- FTA-MW-14
- FTA-MW-206
- FTA-MW-210
- DP-35

Data collected between 2012 and 2016 were included.

4.1.3 Surface Water and Sediment

Exposure to surface water and sediment was evaluated for the 3.26-acre wetland area. Receptors are not likely to be exposed to one area of the wetland more than to another. Therefore, the wetland area was evaluated as one exposure area in the HHRA.

4.2 Determination of Exposure Point Concentrations

To evaluate the magnitude of potential human exposures, the concentration of each COPC in each exposure medium/area is estimated. An estimate of this concentration is referred to as an EPC. EPCs for evaluation of the reasonable maximum exposure (RME) and central tendency exposure (CTE) scenarios for each dataset were calculated as described in the following sections.

4.2.1 Soil, Groundwater, Surface Water, and Sediment

For RME and CTE scenarios, soil, groundwater, surface water, and sediment EPCs are equal to the upper confidence limit (UCL) or the maximum concentration, whichever is lower

(USEPA 2002b). USEPA's ProUCL Version 5.1 software (USEPA 2016h) was used to calculate the ProUCL-recommended UCL.

Based on information presented in the ProUCL guidance (USEPA 2015) regarding minimum sample size and frequency detection, UCLs were calculated where at least 10 samples and at least 6 detects are available. **Attachment B** presents the ProUCL input and output sheets.

When the minimum sample size and number of detects were not met for a dataset, or if the UCL was greater than the maximum detected concentration, the maximum detected concentration was used as the EPC for the RME scenario and the arithmetic mean concentration was used as the EPC for the CTE scenario. The EPCs for COPCs in soil, groundwater, surface water, and sediment are presented in **Tables 3.1.RME/CTE** through **3.4.RME/CTE**.

Separate EPCs were developed for surface soil and subsurface soil. Recreational users, outdoor industrial workers, and hypothetical on-site residents are assumed to be exposed to surface soil. Therefore, surface soil EPCs are applicable to the current scenario. However, under future conditions, redevelopment could result in mixing of surface and subsurface soil, or re-grading, potentially exposing subsurface soil as surface soil. Given the uncertainty surrounding hypothetical future mixing and/or grading of site soils, two future scenarios were evaluated, one in which receptors are potentially exposed to current surface soil and one in which receptors are potentially exposed to current subsurface soils. These two scenarios were also evaluated for the current/future construction worker, potentially exposed to both surface and subsurface soil.

Separate CTE EPCs were not derived for surface water. With the exception of indeno(1,2,3-cd)pyrene, EPCs for surface water are UCLs or represent the only detected concentration (**Table 3.3.RME/CTE**). The maximum and arithmetic mean concentrations for indeno(1,2,3-cd)pyrene are very similar and the maximum detected concentration was therefore used as the EPC for both the RME and the CTE scenarios. Separate CTE EPCs were not necessary for sediment as UCLs were used for all COPCs (**Table 3.4.RME/CTE**).

4.2.2 Air

EPCs for COPCs in fugitive dust (outdoor air), trench air, shower air, and indoor air via the vapor intrusion pathway were estimated based on soil or groundwater EPCs as discussed in the following sections. Supplemental tables and models for the air pathway are presented in **Attachment D**.

4.2.2.1 Fugitive Dust

EPCs for COPCs in fugitive dust (outdoor air) were predicted by combining soil EPCs (calculated as discussed in **Section 4.2.1**) with particulate emission factors (PEFs) calculated in accordance with USEPA guidance (2002a). PEFs were conservatively calculated based on the total size of the FTA (10.27 acres).

The PEF of 6.5×10^8 cubic meters per kilogram (m^3/kg) for recreational users, outdoor workers, and hypothetical future residential receptors was calculated in accordance with USEPA guidance (2002a) in **Attachment D**, Table D-1 based on default inputs for a wind-driven/non-excavation scenario and climate inputs representative of Portland, Maine (USEPA 2002a, Exhibit 5-2).

The PEF of 9.4×10^5 m^3/kg for construction workers was calculated in **Attachment D**, Table D-2, based on default inputs for an unpaved road traffic scenario and climate inputs representative of Portland, Maine (USEPA 2002a, Exhibit 5-2).

Fugitive dust EPCs are not presented separately, as the PEF is applied to the soil EPC in the risk calculations (**Attachment E**, RAGS Part D Table 7s).

4.2.2.2 Trench Air

Excavation trench air concentrations of COPCs resulting from volatilization from groundwater infiltrating an excavation trench were modeled by the use of the method recommended by USEPA (1994) for predicting volatilization from standing water. The trench air concentrations were used for evaluation of the current/future construction worker receptor. The trench model used to estimate trench air EPCs is discussed in **Attachment D**, and the calculations are presented in **Attachment D**, Table D-3. Trench air EPCs are presented in **Table 3.5.RME/CTE**.

4.2.2.3 Shower Air

For evaluation of the bathing/showering pathway, concentrations of volatiles in the shower were modeled using the Foster and Chrostowski (1987) shower model. The shower model was used to estimate the concentrations in shower air resulting from groundwater EPCs. The shower model used to estimate shower air EPCs is discussed in **Attachment D**, and the calculations are presented in **Attachment D**, Table D-4. Shower air EPCs are presented in **Table 3.6.RME/CTE**.

4.2.2.4 Indoor Air

Indoor air EPCs were estimated based on the groundwater EPCs using the USEPA Johnson and Ettinger (JE) Model Spreadsheets and User's Guide (USEPA 2004b,c). RME groundwater EPCs were used as they are the same for hexachlorocyclopentadiene and vinyl chloride, and similar for trichloroethene (10 µg/L RME vs. 8.2 µg/L CTE).

Project-specific information was used in the JE model where available. Where site-specific information was not available, default model inputs were used. Key inputs used in the model are as follows:

- An average soil/groundwater temperature of 7 degrees Celsius was used in the model. This is the default value recommended for Maine on Figure 8 of the USEPA JE Model Guidance (USEPA 2004c). Default soil properties for loamy sand provided in the JE model were used.
- The loamy sand soil type was chosen for use in the JE models, based on shallow site soils, which consist of a mixture of silt, sand, and gravel.
- A depth to water of 2.4 ft was used in the JE models based on the lowest average depth to water measurements obtained from sampling events in Fall 2012, June 2015, and September 2015 for wells included in the HHRA. The average depth to groundwater for each well is listed as follows:

Well Identification	**Average Depth to Groundwater in feet (Fall 2012, June 2015, September 2015)**
DP-35	7.5
MW-1	6.9
MW-5	8.5
MW-9	3.4
MW-10	2.9
MW-11	2.8
MW-12	4.4
MW-14	3.3
MW-206	2.4
MW-210	3.0

- It was assumed that buildings constructed under a hypothetical future use scenario would have a basement, typically assumed to be the model default of 200 centimeters (cm). However, the model requires that the depth to water table (74 cm) minus capillary fringe thickness (18.75 cm) must be greater than the depth to bottom of floor. Due to the shallow depth to water, the default of 200 cm was adjusted to 55 cm to meet the model requirement (74 cm – 18.75 cm = 55.25 cm).
  - The model's default indoor air exchange rate of 0.25 exchanges per hour was used for a residential building scenario. An indoor air exchange rate of 1 exchange per hour was used for an industrial building scenario (CalEPA 2011).
  - The default average vapor flow rate into a building recommended in the model (5 liters per minute) was conservatively used for both a residential and industrial building scenario.

The JE model spreadsheets are presented in **Attachment D**. Indoor air EPCs are presented in **Table 3.7.RME/CTE** (hypothetical future residential scenario) and **Table 3.8.RME/CTE** (future industrial scenario). The only difference between the residential and industrial indoor air modeling is the air exchange rate (as discussed previously). Therefore, the industrial indoor air EPCs were derived by dividing the residential indoor air EPCs by four (0.25/1).

4.3 Exposure Assessment

The purpose of the exposure assessment is the quantification of the extent, frequency, and duration of actual or potential exposure to chemicals by pathways relevant to the site and activities of the potential receptors. As part of the exposure assessment, current and potential future exposure pathways were determined through the identified populations, which may potentially be exposed to COPCs at the site.

An exposure pathway describes the course a chemical follows while moving through environmental media to the receptor. An exposure pathway may consist of a mechanism of release of chemicals to an environmental medium (e.g., soil), an exposure route (e.g., ingestion), and a receptor (e.g., construction worker). An exposure pathway is considered complete when contact by a receptor with impacted media may occur under current site conditions or in the future. USEPA guidance (1989, 1991) requires that plausible exposures under both current and future land use scenarios be evaluated in an HHRA. **Table 1** presents a summary of the current and potential future exposure routes quantitatively evaluated in the HHRA and the human receptors.

The receptors and exposure pathways evaluated in the HHRA based on current and potential future land use are discussed as follows. These exposure pathways are based on the site-specific CSM discussed in **Section 3.1**. Exposure pathways were also identified to be consistent with those assessed for VLF Peninsula/SYA, as applicable. For future land-use scenarios, it is assumed that there would be some level of construction to convert the area to the desired use. Therefore, it is assumed that current subsurface soils may be brought to the surface and become available for exposure by future receptors.

The quantitative exposure assumptions used for evaluation in the HHRA were developed based on professional judgement and the recommended default exposure assumptions by MEDEP/CDC (2013) and USEPA (2014a). Exposure assumptions in the HHRA were also developed to be consistent with those used in the Site 4/VLF Peninsula risk assessment and the SYA HHRA (Resolution 2016a,b), unless site-specific conditions warrant use of alternate exposure assumptions for evaluation of potential exposures at the FTA. The exposure assumptions used in the HHRA are presented in **Tables 4.1.RME/CTE** through **4.16.RME/CTE**.

4.3.1 Current/Future Construction Worker

A construction worker exposure scenario was evaluated in the HHRA assuming that construction or maintenance activities may occur at the FTA as described in **Section 3.1**. The exposure pathways evaluated for a construction worker are as follows:

- Exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air.
- Exposure to groundwater in an excavation trench through incidental ingestion, dermal contact, and inhalation of air within the trench.
- Exposure to surface water and sediment through incidental ingestion and dermal contact. Inhalation of airborne particles in outdoor air is not considered complete/significant for the sediment exposure pathway due to the relatively high percent moisture content of sediment.

The construction worker exposure factors used in the HHRA for the RME and CTE scenarios are presented in **Tables 4.1.RME/CTE** through **4.5.RME/CTE**. A summary of key exposure factors used for evaluation of the RME scenario are discussed as follows.

The construction worker exposure scenario evaluated in this HHRA is conservatively based on recommended exposure assumptions provided by MEDEP/CDC and professional judgement. Therefore, it is likely that use of these recommended exposure assumptions may overestimate potential risk to current/future construction workers. It was conservatively assumed that construction workers may be working on site and potentially exposed to soil for 250 days per year (5 days per week for a 1-year project) for 8 hours per day; and groundwater in an excavation trench for 26 days per year (1 day per week for 26 weeks per year) for 4 hours per day (MEDEP/CDC 2013). It was also conservatively assumed that a construction worker at the FTA may contact surface water and sediment in the wetland area for 30 days per year for 2.6 hours per day, assuming he/she may be performing excavation/regrading activities along the wetland for 5 days per week for 6 weeks. Consistent with MEDEP/CDC (2013) an averaging time of 6 months was used for the construction worker. The exposure assumptions for surface water and sediment were determined based on professional judgment consistent with the VLF Peninsula/SYA HHRAs (Resolution 2016a,b) and assuming MEDEP/CDC's recommended exposure time for a surface water/sediment wading scenario. Given how shallow surface water is in the wetland (maximum depth of 6 inches, as discussed in **Section 3.1**), the wading exposure assumptions are overly conservative. The fraction of soil and sediment ingested from the site was assumed to be 100 percent (%). USEPA's recommended soil ingestion rate for a construction worker of 330 mg/day (USEPA 2002a) was conservatively used for both soil and sediment (note that ½ of the RME rate was assumed for CTE). Workers were conservatively assumed to contact soil,

groundwater, surface water, and sediment with 3,527 cm^2 of body surface area (USEPA 2014a), which represents contact with the head, hands, and forearms. A soil-to-skin adherence factor of 0.3 milligram per cubic centimeter per day (mg/cm^2-day) was used (MEDEP/CDC 2013; USEPA 2002a) for both soil and sediment evaluations. This value is a 95th percentile weighted soil adherence factor for construction workers. In accordance with MEDEP's recommended exposure assumptions (MEDEP/CDC 2013), the adherence factor for sediment was assumed equal to that for soil. The assumption of 100% fraction ingested, and the use of soil intake factors for sediment are very conservative and are used only in the absence of more specific information regarding potential future excavation activities. Furthermore, as noted previously, the use of unfiltered groundwater and surface water data for the dermal contact pathway is conservative.

Inhalation of soil-derived particulates was evaluated for the soil fugitive dust inhalation pathway using the PEF for an unpaved road traffic scenario and climate inputs representative of Portland, Maine (USEPA 2002a, Exhibit 5-2) as described in **Section 4.2.2.1**.

The combination of several conservative exposure assumptions for the construction worker likely leads to an exposure estimate greater than the RME. These conservative assumptions are used only in the absence of more specific information regarding potential future excavation activities.

4.3.2 Current/Future On-Site Recreational User/Trespasser

For the purposes of the HHRA, it was conservatively assumed that humans may trespass onto the site and access soil at the site, in addition to surface water and sediment in the wetland area in a wading exposure scenario. Therefore, a current/future recreational user exposure scenario was evaluated in the HHRA to be protective of both a current trespasser exposure scenario and a future recreational use exposure scenario, assuming access to the area is unrestricted in the future and becomes accessible for recreational use. However, as noted previously, trespassing under the currently scenario is extremely unlikely given the level of security at the station, and there are no plans to open the site for future recreational use.

Under a current scenario, trespassers/recreational users are assumed to be exposed to surface soil, and not subsurface soil. However, exposure to subsurface soil was evaluated in the HHRA assuming subsurface soils may be brought to the surface and become available for exposure under a future-use scenario.

The HHRA evaluated a current/future on-site recreational adult/child user/trespasser for the following pathways:

- Exposure to surface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air (current/future use scenario).
- Exposure to subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air (future use scenario).
- Exposure to surface water and sediment through incidental ingestion and dermal contact. As noted previously, inhalation of airborne particles in outdoor air is not considered complete/significant for the sediment exposure pathway due to the relatively high percent moisture content of sediment.

The on-site recreational user/trespasser exposure factors used in the HHRA for the RME and CTE scenarios are presented in **Tables 4.6.RME/CTE** through **4.8.RME/CTE**. A summary of key exposure factors used for evaluation of the RME scenario is discussed as follows.

It was conservatively assumed that adult and child recreational users may engage in activities resulting in soil exposure for 90 days per year (3 days per week for 30 weeks [April through October] of the year) for 2 hours per day, based on MEDEP's recommended default exposure scenario for a park user (MEDEP/CDC 2013). It was also conservatively assumed that adult and child recreational users may contact surface water and sediment in the wetland area for 26 days per year (1 day per week for 26 weeks [the warmer 6 months] of the year), based on professional judgment. Contact with surface water and sediment is assumed to occur for 2.6 hours per day, consistent with MEDEP's recommended default exposure time for a wading scenario (MEDEP/CDC 2013). However, as noted in **Section 3.1**, water depth in the wetland is very shallow, with a maximum of 6 inches measured in 2014. Therefore, contact with surface water is likely to be minimal and the assumption of surface water contact is very conservative.

The ingestion rate for soil and sediment of 100 mg/day for an adult and 200 mg/day for a child (MEDEP/CDC 2013) were used for the RME scenario (note that ½ of the RME rate was assumed for CTE). The fraction of soil and sediment ingested from the site was assumed to be 100%. MEDEP/CDC's recommended exposure assumptions (2013) assume the ingestion rates for sediment are equal to those for soil. Because the default soil ingestion rates represent the total daily intake of soil integrated over a variety of activities and sources, both indoors and outdoors, the assumption of 100% fraction ingested for both soil and sediment is very conservative. The combination of these assumptions results in a combined soil and sediment ingestion rate twice the default daily soil ingestion rate for each receptor. For the inhalation pathway, recreational users were assumed to be involved in outdoor activities resulting in the inhalation of particulates from soil for 2 hours per day (MEDEP/CDC 2013). Inhalation of soil-derived particulates was evaluated for the adult and child recreational user using the PEF for a wind-driven/non-excavation scenario and

climate inputs representative of Portland, Maine (USEPA 2002a, Exhibit 5-2), as described in **Section 4.2.2.1**.

The adult and child recreational users were conservatively assumed to contact soil, surface water, and sediment with 6,032 cm^2 of body surface area and 2,373 cm^2, respectively (USEPA 2014a). Adherence factors of 0.07 mg/cm^2-day for the adult and 0.2 mg/cm^2-day for the child were used for soil and sediment exposures (MEDEP/CDC 2013). MEDEP/CDC's recommended exposure assumptions (2013) assume the adherence factors for sediment are equal to those of soil. The surface area and adherence factor assume exposures to the head, hands, forearms, lower legs, and feet (exposure to the feet was assumed for the child only, assuming a child may walk barefoot). This scenario assumes that an adult would likely be wearing shoes but may contact sediment while kneeling at the edge of the wetland area, for example. As noted previously, the use of unfiltered surface water data for the dermal contact pathway is conservative.

4.3.3 Future Outdoor Industrial Worker

Currently, there are no workers at the FTA. Future land use of the site is likely to remain constant into the future. However, it was conservatively assumed that future receptors may include outdoor industrial workers under a hypothetical scenario in which the area is redeveloped for regular commercial/industrial use. Future outdoor workers are assumed to be exposed to surface soil only. However, exposure to surface soil and subsurface soil was evaluated in the HHRA assuming there would be some level of construction to convert the area to the desired use and subsurface soils may be brought to the surface and become available for exposure. Therefore, the following exposure scenarios were evaluated in the HHRA for a future outdoor industrial worker:

- Exposure to surface or subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air.

The future outdoor industrial worker exposure factors used in the HHRA for the RME and CTE scenarios are presented in **Table 4.9.RME/CTE**. A summary of key exposure factors used for evaluation of the RME scenario are discussed as follows.

It was assumed that a future outdoor industrial worker may be exposed to soil at the site for 150 days per year (assuming exposure occurs 5 days per week for 30 weeks of the year during the seven warmest months of the year [April through October] when the soil is not frozen or covered by snow/ice) for a duration of 25 years (MEDEP/CDC 2013). The fraction of soil ingested from the site was assumed to be 100%. The default worker soil ingestion rate of 100 mg/kg (USEPA 2014a) was used (note that ½ of the RME rate was assumed for CTE). For the soil fugitive dust inhalation pathway, a worker was assumed to be involved in activities resulting in the inhalation of particulates from soil (i.e., fugitive dust) for 8 hours per day (USEPA 2002a). Inhalation of soil-derived particulates was evaluated for an outdoor industrial worker using the PEF for a

wind-driven/non-excavation scenario and climate inputs representative of Portland, Maine (USEPA 2002a, Exhibit 5-2) as described in **Section 4.2.2.1**.

An outdoor industrial worker was assumed to contact soil with 3,527 cm^2 of body surface area (USEPA 2014a), which represents contact with the head, hands, and forearms. A default worker adherence factor of 0.12 mg/cm^2-day was used (USEPA 2014a) based on contact with soil by hands, forearms, and face.

4.3.4 Future Indoor Industrial Worker

Currently, there are no workers at the FTA. Future land use of the site is likely to remain constant into the future. However, it was conservatively assumed that future receptors may include indoor industrial workers under a hypothetical scenario in which the area is redeveloped for regular commercial/industrial use and buildings are constructed and occupied on a full-time basis. Therefore, future indoor industrial workers were evaluated in the HHRA assuming they may be exposed to volatiles in groundwater that may migrate to the indoor air of overlying buildings via the vapor intrusion pathway.

The future indoor industrial worker exposure factors used in the HHRA for the RME and CTE scenarios are presented in **Table 4.10.RME/CTE**. For the RME scenario, it was assumed that a future indoor industrial worker may be exposed to indoor air within buildings at the site for 8 hours per day, 250 days per year (assuming exposure occurs 5 days per week for 50 weeks of the year), for a duration of 25 years (MEDEP/CDC 2013).

The vapor intrusion pathway evaluation conducted in this HHRA is considered to be a conservative/preliminary evaluation, as further discussed in the uncertainty assessment (**Section 4.7**). Following the results of the HHRA for this exposure pathway, additional recommendations may be made for further evaluation of this potential pathway.

4.3.5 Hypothetical Future On-Site Resident

There are currently no residential receptors on the site, and the site is not zoned for residential use and is not likely to be in the future. However, a residential adult/child exposure scenario was evaluated in the HHRA as a conservative measure of hypothetical future site use to provide information for decision-making purposes. It is assumed that there would be some level of construction to convert the area to the desired use, therefore, subsurface soils may be brought to the surface and become available for exposure under a hypothetical future land use scenario. Therefore, the following exposure scenarios were evaluated in the HHRA for a hypothetical future resident:

- Exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air.
- Exposure to groundwater through ingestion of drinking water and dermal contact, and inhalation during bathing.
- Exposure to indoor air via volatilization from groundwater (i.e., vapor intrusion).
- Exposure to surface water and sediment through incidental ingestion and dermal contact. As noted previously, inhalation of airborne particles in outdoor air is not considered complete/significant for the sediment exposure pathway due to the relatively high percent moisture content of sediment.

The hypothetical future on-site resident exposure factors used in the HHRA for the RME and CTE scenarios are presented in **Tables 4.11.RME/CTE** through **4.16.RME/CTE**. A summary of key exposure factors used for evaluation of the RME scenario are discussed as follows.

Total residential exposure duration is assumed to be 26 years, assuming 6 years as a young child and 20 years as an adult (USEPA 2014a). It was assumed that the child and adult resident may engage in activities resulting in soil exposures 150 days per year (assuming exposure occurs 5 days per week for 30 weeks of the year during the seven warmest months of the year [April through October] when the soil is not frozen or covered by snow/ice) (MEDEP/CDC 2013). This does not imply that people are not outdoors on these days; rather that soils are not available for direct contact on these days. The fraction of soil ingested from the site was assumed to be 100%. The child ingestion rate for soil of 200 mg/day (USEPA 2014a; MEDEP/CDC 2013) was used. The adult ingestion rate for soil of 100 mg/day (USEPA 2014a; MEDEP/CDC 2013) was used for the RME scenario and 50 mg/day was used for the CTE scenario. Note that ½ of the RME rates were assumed for CTE scenario. As noted in **Section 4.3.2**, the combination of the assumptions of 100% fraction ingested from both soil and sediment results in a combined soil and sediment ingestion rate twice the daily assumed soil ingestion rate for each receptor. For the soil inhalation pathway, the child and adult resident were conservatively assumed to be involved in outdoor activities resulting in the inhalation of particulates from soil for 24 hours per day (USEPA 2014a), assuming inhalation of particulates may occur while indoors. Inhalation of soil-derived particulates was evaluated for the adult and child resident using the PEF for a wind-driven/non-excavation scenario and climate inputs representative of Portland, Maine (USEPA 2002a, Exhibit 5-2), as described in **Section 4.2.2.1**.

It was conservatively assumed that the child and adult resident engage in activities resulting in surface water and sediment exposures in the wetland area for 26 days per year (1 day per week for 26 weeks [the warmer 6 months] of the year), based on professional judgment. Contact with surface water and sediment is assumed to occur for 2.6 hours per day, consistent with MEDEP's

recommended default exposure time for a wading scenario (MEDEP/CDC 2013). The fraction of sediment ingested from the site was assumed to be 100%. Sediment ingestion rates of 200 mg/day and 100 mg/day were assumed for the child and adult, respectively (MEDEP/CDC 2013). MEDEP/CDC's recommended exposure assumptions (2013) assume the ingestion rates for sediment are equal to those for soil, which is a very conservative assumption.

The child resident was assumed to contact soil and sediment during outdoor activities with 2,373 cm^2 of body surface area (USEPA 2014a). An adherence factor of 0.2 mg/cm^2-day was used for soil and sediment for the child resident (USEPA 2014a). The adult resident was assumed to contact soil and sediment during outdoor activities with 6,032 cm^2 of body surface area (USEPA 2014a). A soil adherence factor of 0.07 mg/cm^2-day is used for soil and sediment for the adult resident (USEPA 2014a). The child and adult resident surface areas and adherence factors assume exposures to the head, forearms, hands, lower legs, and feet (exposure to the feet was assumed for the child only, assuming a child may walk barefoot). In accordance with MEDEP's recommended exposure assumptions (MEDEP/CDC 2013), the adherence factors for sediment were assumed equal to those for soil.

It was assumed that the child and adult resident engage in activities resulting in groundwater ingestion and bathing/showering exposures 350 days per year (USEPA 2014a, MEDEP/CDC 2013). The drinking water ingestion rate for the child resident was assumed to be 0.78 liters per day (USEPA 2014a) and the drinking water ingestion rate for the adult resident was assumed to be 2.5 liters per day (USEPA 2014a). A showering/bathing exposure time of 0.54 hours per day and a skin surface area of 6,365 cm^2 were assumed for the child resident (USEPA 2014a). A showering/bathing exposure time of 0.71 hours per day and a skin surface area of 19,562 cm^2 were assumed for the adult resident (USEPA 2014a). As noted previously, the use of unfiltered groundwater and surface water data for the dermal contact pathway is conservative.

It was conservatively assumed that the child and adult resident may be exposed to indoor air within their residence for 24 hours per day, 350 days per year (USEPA 2014a, MEDEP/CDC 2013). The vapor intrusion pathway evaluation conducted in this HHRA is considered to be a conservative/preliminary evaluation, as further discussed in the uncertainty assessment (**Section 4.7**). Following the results of the HHRA for this exposure pathway, additional recommendations may be made for further evaluation of this potential pathway.

4.4 Calculation of Dose

The purpose of the exposure assessment is to identify exposure equations to be used in the risk assessment and to document assumptions made for each parameter used in these equations. USEPA guidance documents used in this exposure assessment include RAGS Part A (USEPA 1989); Exposure Factors Handbook (USEPA 2011); Supplemental Guidance for Developing

Soil Screening Levels for Superfund Sites (USEPA 2002a); RAGS Part E (Supplemental Guidance for Dermal Risk Assessment) (USEPA 2004a); RAGS Part F (Supplemental Guidance for Inhalation Risk Assessment) (USEPA 2009) and Supplemental Guidance: Update of Standard Default Exposure Factors (USEPA 2014a).

Equations are presented for the calculation of chronic daily intake values for the ingestion, dermal contact, and inhalation exposure pathways. The equations are used for calculating a lifetime average daily dose (LADD) relevant to cancer risk (i.e., cancer intake) or for calculating an average daily dose (ADD) relevant to noncancer hazard (i.e., noncancer intake). The medium-specific equations used for the calculation of carcinogenic and noncarcinogenic intakes of the COPCs are presented in **Tables 4.1.RME/CTE** through **4.16.RME/CTE**. Absorption factors for soil and sediment are presented in **Attachment C**, Table C-1, and parameters used in the calculation of dermal dose for groundwater and surface water are presented in **Attachment C**, Table C-2. Dermal doses were not calculated for PAHs, PCBs, PFOS, and PFOA. The dermal contact pathway associated with these COPCs in water is considered negligible, as further discussed in **Section 4.7.5**, and was therefore not quantitatively evaluated in the HHRA.

The exposure parameters used for each receptor evaluated in the HHRA are presented in **Tables 4.1.RME/CTE** through **4.16.RME/CTE**, as discussed in **Section 4.3**.

4.5 Toxicity Assessment

The toxicity assessment was conducted in accordance with USEPA guidance and considers chronic (long-term) and subchronic [fewer than 7 years (USEPA 1989)] exposures for carcinogenic and noncarcinogenic COPCs. The USEPA's guidance regarding the hierarchy of sources of human health dose-response values in risk assessment was followed (USEPA 2003) and is presented as follows:

- *Tier 1:* USEPA's Integrated Risk Information System (IRIS) (USEPA 2016i).
- *Tier 2:* Provisional Peer-Reviewed Toxicity Values obtained from USEPA via the USEPA National Center for Environmental Assessment in Cincinnati, Ohio (USEPA 2016j).
- *Tier 3:* Other sources of dose-response values including, but not limited to, California Environmental Protection Agency's Office of Environmental Health and Hazard Assessment Toxicity Criteria Database (CalEPA 2016), minimal risk levels published by the Agency for Toxic Substances and Disease Registry (ATSDR 2016), and the Health Effects Assessment Summary Tables (USEPA 1997).

Where published dose-response values were not available for a chemical, dose-response values based on surrogate chemicals (i.e., chemicals with structural similarities) were identified. The chosen surrogate is referenced in the summary table(s) of dose-response values (**Tables 5.1**, **5.2**, **6.1**, and **6.2**).

4.5.1 Total PCBs

Cancer toxicity values for Total PCBs (high risk and persistence) recommended in USEPA's IRIS database (2016i) were used for evaluation of Total PCBs. For the RME scenario, the upper-bound slope factor was used, and for the CTE scenario, the central tendency estimate slope factor was used. The oral RfD for PCB Aroclor-1254 (USEPA 2016i) was used to evaluate noncarcinogenic oral/dermal pathways. **Section 4.7.4** provides a discussion of the uncertainty associated with the use of the RfD for PCB Aroclor-1254.

4.5.2 Toxicity Information for Noncarcinogenic Effects

Systemic toxic effects other than cancer can be associated with exposures to chemicals. RfDs for oral exposures, and reference concentrations (RfCs) for inhalation exposures, are the toxicity values that are used to evaluate the potential of developing noncarcinogenic effects because of exposure to potentially toxic chemicals. RfDs and RfCs were developed on the premise that there are protective mechanisms that must be overcome before an appreciable risk of adverse health effects is manifested during a defined exposure period. It is assumed that there is a threshold dose that must be exceeded before adverse effects can occur.

Chemicals classified as carcinogens may also produce other systemic effects. These chemicals were also evaluated for potential noncarcinogenic toxic effects and were included in the determination of chronic toxicity HQs, which characterize noncancer hazards. Carcinogenic effects, however, are usually manifested at levels that are significantly lower than those associated with systemic toxic effects; thus, cancer is usually the predominant adverse effect for chemicals that may elicit carcinogenic and noncarcinogenic responses.

Table 5.1 summarizes the oral noncarcinogenic toxicity values (i.e., RfDs) and the corresponding critical effects for the COPCs at the site. This table contains both chronic and subchronic toxicity values. Subchronic toxicity values are applicable to the construction worker scenario where exposures are expected to occur over a brief (e.g., 1-year) duration. Chronic toxicity values are applicable to all other receptors whose exposures are expected to occur over a longer interval of time. Subchronic toxicity values are not generally found in IRIS. Instead, subchronic toxicity values were obtained from chronic toxicity values or from Tier II or Tier III sources. According to USEPA guidance (1989), if a chronic toxicity value was developed based on subchronic data, a subchronic toxicity value may be obtained by removal of the uncertainty factor used to extrapolate from subchronic to chronic exposures (typically a factor of 10). If subchronic data are not available and the chronic toxicity value is derived from chronic data, the chronic toxicity value is adopted as the subchronic toxicity value. **Table 5.2** summarizes the inhalation noncarcinogenic toxicity values (i.e., RfCs) and the corresponding critical effects for COPCs at the site.

4.5.3 Toxicity Information for Carcinogenic Effects

The potential for human carcinogenic effects is evaluated based on the chemical-specific CSFs and unit risk factors (IUR) values along with the weight-of-evidence classification (categories A through E) of the USEPA. The CSF and IUR values are the toxicity values that quantitatively define the dose-response relationship of a known or suspected carcinogen. The CSF and IUR values are a mathematical extrapolation of the slope of the dose-response curve from high doses administered to animals (or the exposures observed in epidemiological studies) to the low doses commonly experienced in the environment. The USEPA has developed CSFs and IURs for chemicals classified as carcinogens based on the premise that there is no threshold (i.e., there is no level of exposure below which there is no risk of a carcinogenic effect).

USEPA's *Guidelines for Carcinogen Risk Assessment* (USEPA 2005a) classifies human carcinogenic potential as "known/likely," "cannot be determined," and "not likely" to replace the weight of evidence categories A through E. The guidelines also acknowledge that the mode of action of a carcinogen may involve both threshold and non-threshold mechanisms.

Table 6.1 summarizes the oral CSFs and the corresponding weight-of-evidence classifications. **Table 6.2** summarizes IUR values.

The quantitative evaluation of potential risks for carcinogenic COPCs with a mutagenic mode of action followed the USEPA guidance titled *Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens* (USEPA 2005b). Specifically, the quantification of cancer risks for child receptors involves the use of age-dependent adjustment factors (ADAFs). An ADAF of 10 was used for exposures occurring less than 2 years of age, an ADAF of 3 was used for exposures occurring between 2 and less than 16 years of age, and an ADAF of 1 was used for exposures occurring after 16 years of age (USEPA 2005b). These ADAFs were used to quantify potential cancer risks for the recreational (adult/child) user and resident (adult/child) for all exposure pathways (i.e., ingestion, dermal contact, and inhalation). The worker receptors are assumed to be over 16 years of age; therefore, adjustment factors were not used for the industrial worker and construction worker. COPCs evaluated in this HHRA that are considered to be mutagenic (USEPA 2016i) are benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenz(a,h)anthracene, indeno(1,2,3-cd)pyrene, trichloroethene, and vinyl chloride. Cancer toxicity values for vinyl chloride account for mutagenic action, such that ADAFs are not applied to the cancer risks for vinyl chloride.

4.5.4 Adjustment of Toxicity Factors

No RfDs or CSFs are available for evaluating dermal exposure. Therefore, carcinogenic risks and noncarcinogenic hazards associated with dermal exposure may be evaluated using an oral CSF or RfD adjusted such that the toxicity value is appropriate for the dermal pathway. As detailed by

USEPA (2004a), for purposes of evaluating dermal exposure, it is generally necessary to adjust an oral toxicity factor (i.e., RfD or CSF) from an administered (i.e., applied) dose to an absorbed (i.e., internal) dose. Because the toxicity values for the COPCs at the site are expressed as orally administered doses (i.e., applied or intake-based), it is necessary to adjust both the RfDs and CSFs for these substances in estimating exposure on an absorbed-dose basis when assessing dermal exposure.

The oral RfDs and oral CSFs for each COPC were modified according to the following equations (USEPA 2004a) for use in assessing dermal exposure:

$$RfD_{ABS} = RfD_o \times ABS_{GI}$$

$$SF_{ABS} = SF_o / ABS_{GI}$$

Where:

RfD_{ABS} = Absorbed RfD (i.e., adjusted dermal RfD) (mg/kg-day)

RfD_o = Oral RfD (mg/kg-day)

ABS_{GI} = Fraction of contaminant absorbed in gastrointestinal tract (dimensionless) in critical toxicity study. Absolute oral bioavailability factor for each chemical (i.e., oral to dermal adjustment factor)

SF_{ABS} = Absorbed slope factor (i.e., adjusted dermal slope factor)

SF_o = Oral slope factor $(mg/kg\text{-}day)^{-1}$

Tables 5.1 and **6.1** present the oral to dermal adjustment factors used to adjust the oral toxicity criteria for the COPCs evaluated in the dermal exposure pathways. Oral bioavailability values used were obtained from USEPA guidance (2004a).

4.6 Risk Characterization

Risk characterization combines estimates of exposure with toxicity data to develop estimates of the probability that an adverse effect will occur under the specified conditions of exposure. The risk characterization was divided into three phases: (1) risk estimation, (2) risk description, and (3) uncertainty analysis.

Risk estimation is undertaken by combining the toxicity factors and exposure assessment equations to calculate estimates of risks. Noncarcinogenic hazards are reported as pathway-specific Hazard Indices (HIs), which are the sum of individual COPC HQs for that pathway. A total HI is calculated, as well as HQs from COPCs that affect the same target organ. Estimates of carcinogenic risks are reported as ELCRs. Current practice considers carcinogenic risks to be additive when assessing exposure to a mixture of hazardous substances. Risk description entails several discussions,

including the relative contributions of individual exposure pathways to the total potential risk for each medium. The significance of the risk estimates are relative to risk management criteria set forth in USEPA policy. The uncertainty analysis describes and quantifies, where possible, the impact of data uncertainty and variability, exposure assumptions, and toxicity values on estimates of potential risk.

4.6.1 Estimation of Potential Risk

Noncancer hazard is estimated by means of a HQ. To calculate noncarcinogenic HQs, the ADDs, calculated as described in **Section 4.4**, were divided by the RfDs as follows:

$$HQ = ADD / RfD$$

The sum of this ratio for all chemicals within an exposure point and pathway that have the same target organ or type of toxicity is termed the pathway HI. The HI is useful as a reference point for gauging potential effects of environmental exposures to complex mixtures. In general, HIs that are less than 1 are not of regulatory concern; however, a HI of greater than 1 does not automatically indicate that an adverse effect will occur and should not automatically be interpreted as posing an unacceptable risk to the exposed population. The magnitude of the HQ cannot be directly equated to a probability or effect level.

The total pathway HI for each exposure point was calculated by summing the HQs for all COPCs. Total HIs for each receptor by medium were calculated by summing the total HIs across pathways within the media (e.g., summing dermal and ingestion soil risk estimates). As a first approximation, all COPCs are assumed to have additive effects. Total HIs, assuming additivity of effects, are presented per media and exposure pathway in **Attachment E** (RAGS Part D Table 7s). Additionally, HIs were calculated separately for COPCs that have similar systemic effects (i.e., target organs) for each pathway and medium. Receptor-specific HIs per target organ are presented in **Attachment F** (RAGS Part D Table 9.TEs).

Both USEPA and MEDEP use a target HI per target organ of 1 (USEPA 1991; MEDEP/CDC 2011).

The potential cancer risk for each receptor is estimated for each medium by means of an ELCR. USEPA (1991) states that where the cumulative incremental current or future potential ELCR to an individual is less than 10^{-4}, action generally is not warranted unless there are adverse environmental impacts. MEDEP uses a target ELCR of 10^{-5} (MEDEP/CDC 2011).

To calculate the ELCR, the chemical- and pathway-specific LADDs calculated as described in **Section 4.4** were multiplied by CSFs as follows:

$$ELCR = CSF \times LADD \times ADAF \text{ (where applicable)}$$

The resulting value represents the incremental upper-bound probability that an individual could develop cancer over his or her lifetime due to exposure to potential carcinogens under the conditions specified in the exposure scenario. For example, carcinogenic risk levels of 10^{-6} and 10^{-4} represent an incremental chance of one-in-one-million and one-in-ten-thousand, respectively, that an individual could contract cancer over a lifetime.

The potential cancer risk for each pathway (e.g., the soil ingestion pathway) was calculated by summing the potential risks from each COPC at each exposure point within the pathway, while receptor risks for each medium were calculated by summing ELCRs for each pathway within the medium (e.g., the soil incidental ingestion and dermal contact pathways). Pathway ELCRs are calculated in RAGS Part D Table 7s and are presented in **Attachment E** (Table 7.1.RME/CTE through 7.5.RME/CTE). Total potential ELCRs are calculated per media and exposure pathway in RAGS Part D Table 9s, presented in **Attachment F** (Tables 9.1.RME/CTE through 9.5.RME/CTE).

For each associated exposure scenario (i.e., RME/CTE/receptor/medium) with a potential risk/HI above MEDEP target levels (i.e., total ELCR > 10^{-5}, and total HI > 1 per target endpoint), risk drivers were defined as COPCs with an individual ELCR > 10^{-6} or target organ HI > 1, at one significant figure. Tables showing the total receptor ELCRs and HIs for risk drivers only are presented in **Tables 10.1.RME/CTE** through **10.5.RME/CTE**).

Tables 11.1.RME/CTE through **11.5.RME/CTE** provide summaries of potential ELCRs and noncarcinogenic HIs for each of the receptors evaluated. Potential ELCRs and HIs above MEDEP or USEPA target levels are identified separately to facilitate risk management decisions. **Tables 11.1.RME/CTE** through **11.5.RME/CTE** also list the chemicals identified as risk drivers for each exposure scenario in which the total potential ELCR or total potential HI are above MEDEP target levels (i.e., total ELCR > 10^{-5}, and total HI > 1 per target endpoint), as requested by MEDEP (Tetra Tech 2014).

These risk drivers were further evaluated in conjunction with the results of the background evaluation (included as Appendix C of the RI report and described in **Section 2.2**) to determine if they are site-related or non-site-related (i.e., identified as being consistent with background based on a comparison of concentrations in site and background datasets). **Tables 10.1.RME/CTE** through **10.5.RME/CTE** and **Tables 11.1.RME/CTE** through **11.5.RME/CTE** indicate where a risk driver was identified as consistent with background.

4.6.2 Risk Description

Section 4.6.2 summarizes the human health risks potentially associated with exposures to media associated with the FTA. Individual chemical-specific potential carcinogenic risks are expressed as probabilities of developing cancer (i.e., ELCRs), while noncarcinogenic hazards are expressed as HIs.

Total potential ELCRs and HIs were calculated per receptor by summing the ELCR/HI associated with soil exposure within each of the soil exposure areas, the maximum ELCR/HI associated with exposure to groundwater, and the ELCR/HI associated with surface water and sediment within the wetland area.

4.6.2.1 Description of HI Estimates

HI estimates represent the potential for health effects other than cancer from exposure to chemicals at the site. Total HIs and HIs segregated by target organ were calculated, and evaluated as to whether target organ-specific HIs exceed risk management criteria. **Tables 11.1.RME/CTE** through **11.5.RME/CTE** provide comprehensive summaries of the noncarcinogenic hazards and risk drivers by receptor and media; **Attachment E** and **Attachment F** provide the detailed calculations (RAGS Part D Table 7s and Table 9s).

For the recreational user/trespasser and residential exposure scenarios, the child is the most sensitive receptor for the estimation of noncarcinogenic hazard. Therefore, the child receptor HIs were presented in the risk/hazard summary tables as being protective of the recreational user/trespasser and residential exposure scenarios. However, both the child and adult receptor HIs are presented in **Attachment E** and **Attachment F** (RAGS Part D Table 7s and 9s) for informational purposes and to aid in decision-making.

Current/Future Construction Worker

The total potential HIs for the current/future construction worker based on exposure to soil, groundwater, surface water, and sediment are presented in **Table 11.1.RME/CTE.** The total potential HIs were calculated for surface soil and subsurface soil, groundwater, surface water, and sediment in **Attachment E**, RAGS Part D Table 7.1 RME/CTE and Attachment F, Table 9.1 RME/CTE. Target organ HIs were calculated in **Attachment E**, Table 7.1.TE.RME/CTE. The total potential HI results are summarized by the exposure scenario in the following sections.

RME Scenario

The total potential HIs (based on all target organs combined) and the maximum target organ-specific HIs associated with exposure to soil, groundwater, surface water, and sediment are as follows:

Media	Total HI [a]	
	Soil Exposure Area 1	**Soil Exposure Area 2**
Surface soil Groundwater Wetland surface water and sediment	Total: 30 **Target organ: 30**	8 **Target organ: 4**
Subsurface soil Groundwater Wetland surface water and sediment	Total: 6 **Target organ: 5**	5 **Target organ: 4**

Notes:
Bolded where greater than USEPA and MEDEP's target HI of 1 (per target organ).
[a] Sum of HI estimates for applicable soil exposure area, groundwater, and wetland surface water and sediment.

As indicated in **Table 10.1.RME**, total potential HIs (per target organ) are above USEPA/MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- *Soil Exposure Area 1:* Manganese in surface and subsurface soil
- *Soil Exposure Area 2:* Manganese in surface and subsurface soil, Total PCBs in surface soil

CTE Scenario

The total potential HIs (based on all target organs combined) and the maximum target organ-specific HIs associated with exposure to soil, groundwater, surface water, and sediment are as follows:

Media	Total HI [a]	
	Soil Exposure Area 1	**Soil Exposure Area 2**
Surface soil Groundwater Wetland surface water and sediment	Total: 10 **Target organ: 10**	Total: 3 **Target organ: 2**
Subsurface soil Groundwater Wetland surface water and sediment	Total: 3 **Target organ: 2**	Total: 2 **Target organ:2**

Notes:
Bolded where greater than USEPA and MEDEP's target HI of 1 (per target organ).
[a] Sum of HI estimates for applicable soil exposure area, groundwater, and wetland surface water and sediment.

As indicated in **Table 10.1.CTE**, total potential HIs (per target organ) are above USEPA/MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- *Soil Exposure Area 1:* Manganese in surface and subsurface soil
- *Soil Exposure Area 2:* Manganese in subsurface soil

Current/Future On-Site Recreational User/Trespasser

The total potential HIs for the current/future on-site recreational user/trespasser based on exposure to soil, surface water, and sediment are presented in **Table 11.2.RME/CTE**. The total potential HIs were calculated for surface soil and subsurface soil, surface water, and sediment in **Attachment E**, RAGS Part D Table 7.2 RME/CTE and **Attachment F**, Table 9.2 RME/CTE. Target organ HIs were calculated in **Attachment E**, Table 7.2.TE.RME/CTE. The total potential HI results are summarized by the exposure scenario in the following sections.

RME Scenario

The total potential HIs (based on all target organs combined) and the maximum target organ-specific HIs associated with exposure to soil, surface water, and sediment are as follows:

	Total HI [a]	
Media	**Soil Exposure Area 1**	**Soil Exposure Area 2**
Surface soil Wetland surface water and sediment	Total: 1 Target organ: 0.8	Total: 10 **Target organ: 10**
Subsurface soil Wetland surface water and sediment	Total: 0.7 Target organ: 0.2	Total: 2 **Target organ: 2**

Notes:
Bolded where greater than USEPA and MEDEP's target HI of 1 (per target organ).
[a] Sum of HI estimates for applicable soil exposure area and wetland surface water and sediment.

As indicated in **Table 10.2.RME**, total potential HIs (per target organ) are above USEPA/MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- *Soil Exposure Area 2:* Total PCBs in surface soil

CTE Scenario

The total potential HIs (based on all target organs combined) and the maximum target organ-specific HIs associated with exposure to soil, surface water, and sediment are as follows:

	Total HI [a]	
Media	**Soil Exposure Area 1**	**Soil Exposure Area 2**
Surface soil Wetland surface water and sediment	Total: 0.4 Target organ: 0.2	Total: 3 **Target organ: 2**
Subsurface soil Wetland surface water and sediment	Total: 0.2 Target organ: 0.05	Total: 0.5 Target organ: 0.3

Notes:
Bolded where greater than USEPA and MEDEP's target HI of 1 (per target organ).
[a] Sum of HI estimates for applicable soil exposure area and wetland surface water and sediment.

As indicated in **Table 10.2.CTE**, total potential HIs (per target organ) are above USEPA/MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- *Soil Exposure Area 2:* Total PCBs in surface soil

Future Outdoor Industrial Worker

The total potential HIs for the future outdoor industrial worker based on exposure to soil are presented in **Table 11.3.RME/CTE**. The total potential HIs were calculated for surface soil and subsurface soil in **Attachment E**, RAGS Part D Table 7.3.RME/CTE and **Attachment F,** Table 9.3.RME/CTE. Target organ HIs were calculated in **Attachment E**, Table 7.3.TE.RME/CTE. The total potential HI results are summarized by the exposure scenario in the following sections.

RME Scenario

The total potential HIs (based on all target organs combined) and the maximum target organ-specific HIs associated with exposure to soil are as follows:

	Total HI [a]	
Media	**Soil Exposure Area 1**	**Soil Exposure Area 2**
Surface soil	Total: 0.2 Target organ: 0.1	Total: 2 **Target organ: 2**
Subsurface soil	Total: 0.09 Target organ: 0.03	Total: 0.4 Target organ: 0.3

Notes:
Bolded where greater than USEPA and MEDEP's target HI of 1 (per target organ).
[a] Sum of HI estimates for applicable soil exposure area.

As indicated in **Table 10.3.RME**, total potential HIs (per target organ) are above USEPA/MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- *Soil Exposure Area 2:* Total PCBs in surface soil

CTE Scenario

The total potential HIs (based on all target organs combined) and the maximum target organ-specific HIs associated with exposure to soil are as follows:

Media	Total HI [a]	
	Soil Exposure Area 1	**Soil Exposure Area 2**
Surface soil	Total: 0.1 Target organ: 0.08	Total: 0.8 Target organ: 0.8
Subsurface soil	Total: 0.05 Target organ: 0.02	Total: 0.2 Target organ: 0.1

Note:
[a] Sum of HI estimates for applicable soil exposure area.

Total potential HIs are below USEPA/MEDEP's target HI of 1.

Future Indoor Industrial Worker

The total potential HIs for the future indoor industrial worker based on exposure to volatiles in groundwater via the vapor intrusion pathway are presented in **Table 11.4.RME/CTE.** The associated total potential HIs and target organ HIs were calculated in **Attachment E**, RAGS Part D Tables 7.4.RME/CTE and **Attachment F**, Tables 9.4.RME/CTE. The total potential HI results are summarized by the exposure scenario in the following sections.

RME Scenario

The total potential HI (based on all target organs combined) associated with exposure to volatiles in groundwater via the vapor intrusion pathway is 0.03, less than USEPA/MEDEP's target HI of 1.

CTE Scenario

The total potential HI (based on all target organs combined) associated with exposure to volatiles in groundwater via the vapor intrusion pathway is 0.01, less than USEPA/MEDEP's target HI of 1.

Hypothetical Future On-Site Resident

The total potential HIs for the hypothetical future resident based on exposure to soil, groundwater, surface water, and sediment are presented in **Table 11.5.RME/CTE**. The total potential HIs were calculated for surface soil and subsurface soil, surface water, and sediment in **Attachment E**, RAGS Part D Tables 7.5 RME/CTE and **Attachment F**, Tables 9.5 RME/CTE. Target organ HIs were calculated in **Attachment E**, Tables 7.5.TE.RME/CTE. The total potential HI results are summarized by the exposure scenario in the following sections.

RME Scenario

The total potential HIs (based on all target organs combined) and the maximum target organ-specific HIs associated with exposure to soil, groundwater, surface water, and sediment are as follows:

Media	Total HI [a]	
	Soil Exposure Area 1	**Soil Exposure Area 2**
Surface soil Groundwater Wetland surface water and sediment	Total: 10 **Target organ: 5**	Total: 30 **Target organ: 20**
Subsurface soil Groundwater Wetland surface water and sediment	Total: 10 **Target organ: 4**	Total: 10 **Target organ: 4**

Notes:
Bolded where greater than USEPA and MEDEP's target HI of 1 (per target organ).
[a] Sum of HI estimates for applicable soil exposure area, groundwater, and wetland surface water and sediment.

As indicated in **Table 10.5.RME**, total potential HIs (per target organ) are above USEPA/MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- *Soil Exposure Area 2:* Total PCBs in surface and subsurface soil
- *Groundwater:* Manganese in groundwater

CTE Scenario

The total potential HIs (based on all target organs combined) and the maximum target organ-specific HIs associated with exposure to soil, groundwater, surface water, and sediment are as follows:

Media	Total HI [a]	
	Soil Exposure Area 1	**Soil Exposure Area 2**
Surface soil Groundwater Wetland surface water and sediment	Total: 5 **Target organ: 2**	Total: 9 **Target organ: 4**
Subsurface soil Groundwater Wetland surface water and sediment	Total: 5 **Target organ: 2**	Total: 6 **Target organ: 2**

Notes:
Bolded where greater than USEPA and MEDEP's target HI of 1 (per target organ).
[a] Sum of HI estimates for applicable soil exposure area, groundwater, and wetland surface water and sediment.

As indicated in **Table 10.5.CTE**, total potential HIs (per target organ) are above USEPA/MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- *Soil Exposure Area 2:* Total PCBs in surface soil
- *Groundwater:* Manganese

4.6.2.2 Description of ELCR Estimates

Estimates of ELCR represent the potential risk of cancer from exposure to chemicals at the site. For each receptor, pathway- and medium-specific potential ELCRs for COPCs are summed and presented as total receptor risks. The potential ELCRs for the child and adult recreational user and child and adult resident were summed to present the total potential cancer risk for the current/future recreational user/trespasser and hypothetical future resident, respectively. **Tables 11.1.RME/CTE** through **11.5.RME/CTE** provide comprehensive summaries of the potential carcinogenic risks and risk drivers by receptor and media; **Attachment E** and **Attachment F** provide the detailed calculations (RAGS Part D Table 7s and Table 9s).

Current/Future Construction Worker

The total potential ELCRs for the current/future construction worker based on exposure to soil, groundwater, surface water, and sediment are presented in **Table 11.1.RME/CTE**. The total potential ELCRs were calculated for surface soil and subsurface soil, groundwater, surface water, and sediment in **Attachment E**, Tables 7.1.RME/CTE and **Attachment F**, Tables 9.1.RME/CTE. The total potential ELCR results are summarized by the exposure scenario in the following sections.

RME Scenario

The total potential ELCR associated with exposure to soil, groundwater, surface water, and sediment are as follows:

	Total Potential ELCR [a]	
Media	**Soil Exposure Area 1**	**Soil Exposure Area 2**
Surface soil Groundwater Wetland surface water and sediment	1×10^{-6}	4×10^{-6}
Subsurface soil Groundwater Wetland surface water and sediment	1×10^{-6}	1×10^{-6}

Note:
[a] Sum of ELCR estimates for applicable soil exposure area, groundwater, and wetland surface water and sediment.

All total ELCRs for the RME current/future construction worker are within USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Therefore, no risk drivers were selected for this receptor/exposure area based on potential carcinogenic risk.

CTE Scenario

The total potential ELCR associated with exposure to soil, groundwater, surface water, and sediment are as follows:

Media	Total Potential ELCR [a]	
	Soil Exposure Area 1	**Soil Exposure Area 2**
Surface soil Groundwater Wetland surface water and sediment	3×10^{-7}	7×10^{-7}
Subsurface soil Groundwater Wetland surface water and sediment	3×10^{-7}	4×10^{-7}

Note:
[a] Sum of ELCR estimates for applicable soil exposure area, groundwater, and wetland surface water and sediment.

All total ELCRs for the CTE current/future construction worker are within USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Therefore, no risk drivers were selected for this receptor/exposure area based on potential carcinogenic risk.

Current/Future On-Site Recreational User/Trespasser

The total potential ELCRs for the current/future on-site recreational user/trespasser based on exposure to soil, surface water, and sediment are presented in **Table 11.2.RME/CTE**. The total potential ELCRs were calculated for surface soil and subsurface soil, surface water, and sediment in **Attachment E**, RAGS Part D Tables 7.2.RME/CTE and **Attachment F**, Tables 9.2.RME/CTE. The total potential ELCR results are summarized by the exposure scenario in the following sections.

RME Scenario

The total potential ELCR associated with exposure to soil, surface water, and sediment are as follows:

Media	Total Potential ELCR [a]	
	Soil Exposure Area 1	**Soil Exposure Area 2**
Surface soil Wetland surface water and sediment	6×10^{-6}	**6×10^{-5}**
Subsurface soil Wetland surface water and sediment	6×10^{-6}	1×10^{-5}

Notes:
Bolded where greater than USEPA and MEDEP's target ELCR of 10^{-5}.
[a] Sum of ELCR estimates for applicable soil exposure area and wetland surface water and sediment.

The total ELCRs for the RME current/future recreational user/trespasser are within USEPA's target ELCR range of 10^{-6} to 10^{-4} for all areas. Therefore, no risk drivers are identified based on potential carcinogenic risk for these exposure areas utilizing USEPA guidance. As indicted in

Table 10.2.RME, total ELCRs are above MEDEP's target ELCR of 10^{-5} within the following exposure areas and media based on the following chemicals:

- *Soil Exposure Area 2:* Total PCBs, benzo(a)pyrene, and arsenic in surface soil

CTE Scenario

The total potential ELCR associated with exposure to soil, surface water, and sediment are as follows:

Media	Total Potential ELCR [a]	
	Soil Exposure Area 1	**Soil Exposure Area 2**
Surface soil Wetland surface water and sediment	4×10^{-7}	3×10^{-6}
Subsurface soil Wetland surface water and sediment	5×10^{-7}	8×10^{-7}

Note:
[a] Sum of ELCR estimates for applicable soil exposure area and wetland surface water and sediment.

All total ELCRs for the CTE current/future recreational user/trespasser are within USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Therefore, no risk drivers are identified for this receptor in these exposure areas based on potential carcinogenic risk.

Future Outdoor Industrial Worker

The total potential ELCRs for the future outdoor industrial worker based on exposure to soil are presented in **Table 11.3.RME/CTE**. The total potential ELCRs were calculated for surface soil and subsurface soil in **Attachment E**, RAGS Part D Tables 7.3.RME/CTE and **Attachment F**, RAGS Part D Tables 9.3.RME/CTE. The total potential ELCR results are summarized by the exposure scenario in the following sections.

RME Scenario

The total potential ELCR associated with exposure to soil are as follows:

Media	Total Potential ELCR [a]	
	Soil Exposure Area 1	**Soil Exposure Area 2**
Surface soil	2×10^{-6}	**3×10^{-5}**
Subsurface soil	2×10^{-6}	6×10^{-6}

Notes:
Bolded where greater than USEPA and MEDEP's target ELCR of 10^{-5}.
[a] Sum of ELCR estimates for applicable soil exposure area.

The total ELCRs for the RME future outdoor industrial worker are within USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target of 10^{-5} for Soil Exposure Area 1. Therefore, no risk drivers are identified based on potential carcinogenic risk for this exposure area. As indicted in **Table 10.3.RME**, total ELCRs are above MEDEP's target ELCR of 10^{-5} in Soil Exposure Area 2 surface soil for following chemicals:

- *Soil Exposure Area 2:* Total PCBs arsenic in surface soil

CTE Scenario

The total potential ELCR associated with exposure to soil are as follows:

	Total Potential ELCR [a]	
Media	**Soil Exposure Area 1**	**Soil Exposure Area 2**
Surface soil	3×10^{-7}	2×10^{-6}
Subsurface soil	3×10^{-7}	7×10^{-7}

Note:
[a] Sum of ELCR estimates for applicable soil exposure area.

All total ELCRs for the CTE future outdoor industrial worker are below USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Therefore, no risk drivers are identified based on potential carcinogenic risk for these exposure areas.

Future Indoor Industrial Worker

The total potential ELCRs for the future indoor industrial worker based on exposure to volatiles in groundwater via the vapor intrusion pathway are presented in **Table 11.4.RME/CTE.** The associated total potential ELCRs were calculated in **Attachment E**, RAGS Part D Tables 7.4.RME/CTE and **Attachment F**, RAGS Part D Tables 9.4.RME/CTE. The total potential ELCR results are summarized by the exposure scenario in the following sections.

RME Scenario

The total potential ELCR for the RME future indoor industrial worker of 1×10^{-7} is below USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Therefore, no risk drivers are identified based on potential carcinogenic risk for vapor intrusion.

CTE Scenario

The total potential ELCR for the RME future indoor industrial worker of 5×10^{-8} is below USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Therefore, no risk drivers are identified based on potential carcinogenic risk for vapor intrusion.

Hypothetical Future On-Site Resident

The total potential ELCRs for the hypothetical future on-site resident based on exposure to soil, groundwater, surface water, and sediment are presented in **Table 11.5.RME/CTE.** The total potential ELCRs were calculated for surface soil and subsurface soil, groundwater surface water, and sediment in **Attachment E**, RAGS Part D Tables 7.5.RME/CTE (adult), Table 7.5.RME/CTE (child), and **Attachment F**, RAGS Part D Table 9.5.RME/CTE. The total potential ELCR results are summarized by the exposure scenario in the following sections.

RME Scenario

The total potential ELCR associated with exposure to soil, groundwater, surface water, and sediment are as follows:

	Total Potential ELCR [a]	
Media	**Soil Exposure Area 1**	**Soil Exposure Area 2**
Surface soil Groundwater Wetland surface water and sediment	**2×10^{-4}**	**3×10^{-4}**
Subsurface soil Groundwater Wetland surface water and sediment	**2×10^{-4}**	**2×10^{-4}**

Notes:
Bolded where greater than MEDEP's target ELCR of 10^{-5} and greater than USEPA's target ELCR range of 10^{-6} to 10^{-4}.
[a] Sum of ELCR estimates for applicable soil exposure area, groundwater, and wetland surface water and sediment.

As indicated in **Table 10.5.RME**, total ELCRs are within or above USEPA's target ELCR range of 10^{-6} to 10^{-4} and are above MEDEP's target ELCR of 10^{-5} within the following exposure areas and media based on the following chemicals:

- *Soil Exposure Area 1:* Arsenic in surface and subsurface soil
- *Soil Exposure Area 2:* Total PCBs and arsenic in surface and subsurface soil. Benzo(a)pyrene in surface soil
- *Groundwater:* Trichloroethene, vinyl chloride, and arsenic

CTE Scenario

The total potential ELCR associated with exposure to soil, groundwater, surface water, and sediment are as follows:

Media	Total Potential ELCR [a]	
	Soil Exposure Area 1	**Soil Exposure Area 2**
Surface soil Groundwater Wetland surface water and sediment	**3×10^{-5}**	**3×10^{-5}**
Subsurface soil Groundwater Wetland surface water and sediment	**3×10^{-5}**	**3×10^{-5}**

Notes:
Bolded where greater than MEDEP's target ELCR of 10^{-5}.
[a] Sum of ELCR estimates for applicable soil exposure area, groundwater, and wetland surface water and sediment.

Total ELCRs are below USEPA's target ELCR range of 10^{-6} to 10^{-4}. As indicated in **Table 10.5.CTE**, total ELCRs are above MEDEP's target ELCR of 10^{-5} within the following exposure areas and media based on the following chemicals:

- *Soil Exposure Area 2:* Total PCBs in surface soil
- *Groundwater:* Trichloroethene and arsenic

4.6.2.3 Background Evaluation

The HHRA results discussed in **Section 4.6.2.1** identified the following risk drivers for one or more receptors/exposure areas:

- *Soil Exposure Area 1:* Arsenic and manganese in surface and subsurface soil
- *Soil Exposure Area 2:* Total PCBs, arsenic, manganese in surface and subsurface soil, and benzo(a)pyrene in surface soil
- *Groundwater:* Trichloroethene, vinyl chloride, arsenic, and manganese

Tables 10.1.RME/CTE to **10.5.RME/CTE** present the potential risk and HI estimates for the risk drivers. Table 10 is only presented for receptor scenarios where receptor scenarios where risk drivers were identified. Therefore, there are gaps in the numbering (e.g., there are no risk drivers for the indoor worker, and therefore, no Table 10.4 is presented).

The risk drivers were further evaluated in conjunction with the results of the background evaluation (included as Appendix C of the RI report and described in **Section 2.2**) to determine if they are site-related or non-site-related (i.e., identified as being consistent with background based on a comparison of concentrations in site and background datasets).

The following risk drivers identified based on the HHRA results were found to have concentrations in site media less than or consistent with concentrations in background and are therefore not considered site-related COCs for the FTA:

- *Soil Exposure Area 1 Surface Soil:* Arsenic
- *Soil Exposure Area 1 Subsurface Soil:* Arsenic
- *Soil Exposure Area 2 Surface Soil:* Arsenic

4.7 Description of Uncertainties

Estimation of potential risks to human health that may result from exposure to chemicals in the environment is a complex process that often requires the combined efforts of multiple disciplines. Each assumption, whether regarding the toxicity value to use for a particular chemical or the value of a parameter in an exposure equation, has a degree of variability and uncertainty associated with it. In each step of the risk assessment process, beginning with the data collection and analysis and continuing through the toxicity assessment, exposure assessment, and risk characterization, conservative assumptions are made that are intended to be protective of human health and to ensure that risks are not underestimated. There is a probability of overestimating health risks or hazards for a number of reasons. The following subsections provide a discussion of the key uncertainties that may affect the final estimates of human health risk in this HHRA. Uncertainties are arranged by topic.

4.7.1 Environmental Sampling and Analysis

The process of environmental sampling and analysis results in uncertainties from several sources, including errors inherent in sampling procedures or analytical methods. One area of uncertainty is sampling procedures. Since it is not possible to sample the entire area of interest at a given site, several samples are taken from each medium within a site, and the results are considered representative of the chemicals present throughout the site. This assumption may overestimate or underestimate risk.

Analytical methods also involved uncertainties. Due to uncertainty of quantification, individual chemicals were sometimes listed as detected but with the value qualified as estimated by laboratory qualification or validation procedures. The estimated value was used in the HHRA. This uncertainty may either overestimate or underestimate risk depending on how close the estimated value is to the true value.

All available data were reviewed to identify the dataset appropriate for use in the HHRA, as discussed in **Section 2.1**.

Soil data from all available sampling events were included in the HHRA. Although some of the data are over 10 years old, many of the chemicals within these analyte groups are known to be persistent in the environment. Therefore, all soil data in areas that have not been excavated were evaluated in the HHRA. This assumption may result in an over-estimate of potential risk associated with exposure to soil given that it is likely that concentrations of certain chemicals may have decreased over time.

Surface water and sediment data from both 2012 and 2014 were included in the HHRA. The use of both rounds provides two samples per location and a sufficient number of data points for UCL derivation.

Groundwater data collected between 1999 and 2016 are available from both permanent and temporary wells. Consistent with USEPA (2014b), only data from permanent wells were included in the HHRA. USEPA (2014b) recommends that where seasonal trends are absent, the latest two rounds of data from each well, generally from the past year, be used in the HHRA. The hydrograph of groundwater elevation data from 2012 to 2015 (Figure 3-4 of the RI report) reveals no discernable patterns in seasonal groundwater flow patterns. Therefore, the use of multiple rounds of data from the same well was deemed appropriate for this HHRA.

The groundwater dataset used in the HHRA includes data collected from permanent wells between 2012 and 2016 and was selected to be representative of current conditions. Groundwater data collected prior to 2012 were not used in the HHRA as they may not be representative of current conditions. The latest two monitoring rounds at the FTA (June 2014 and June 2015) had slightly varying analyte lists for SVOCs and VOCs; therefore, the November 2012 round was included to ensure adequate data points per chemical and well. The November 2012 data may not be as reflective off current conditions as the more recent rounds.

The HHRA utilizes the total (unfiltered) groundwater and surface water data for oral exposure pathways, consistent with the recommendation in USEPA (2004a). However, as indicated in USEPA (2014a):

> "….particulate-bound chemicals in an aqueous medium (e.g., suspended sediment particles) would be considered to be much less bioavailable for dermal absorption, due to inefficient adsorption of suspended particles onto the skin surface and a slower rate of absorption into the skin. The uncertainty in the estimation of the dermal dose from a water sample with high turbidity is directly proportional to the magnitude of the difference in the concentration between an unfiltered and filtered sample. The actual bioavailable concentration is likely to lie somewhere between the unfiltered and filtered sample concentrations."

Therefore, the use of the unfiltered groundwater and surface water data for the dermal contact pathway is conservative.

4.7.2 Calculation of Total PCBs

PCBs were evaluated in the HHRA as Total PCBs rather than by individual PCB Aroclors, as discussed in **Section 2.3.2**. This approach is commonly used to assess potential risk associated with exposure to PCB concentrations when only PCB Aroclor data are available and is a reasonable approach given the availability of toxicity values for Total PCBs and the similar toxic mechanisms for the class of chemicals. The Total PCB concentrations used in the HHRA are based on the sum of the individual PCB Aroclors detected in each sample. To assess the uncertainties associated with this approach and the potential to underestimate risks due to the presence of elevated DLs in site data, at the request of MEDEP, Total PCB concentrations were also calculated assuming that the non-detect results reported for PCB Aroclors were present at a concentration equal to the associated reporting DL, referred to in this section as the Full DL method. The Full DL method (which was not used in the HHRA calculations presented in prior sections of this report) is considered to overestimate potential risk/hazard since the assumption for all samples is that all individual PCB Aroclors analyzed are present at the reporting DL. However, further evaluation was performed, as discussed by media in the following paragraphs, to determine whether the conclusions of the HHRA would change if the Full DL method was used.

Attachment G presents the associated table referred to in this section. Table G-1 presents a summary of the Total PCB concentrations for each media/sample based on use of the Detects Only versus Full DL methods. The absolute difference in concentrations between the methods is also presented. Table G-1 presents a summary of the comparison of the two methods, discussed in the following paragraphs, for soil, groundwater, surface water, and sediment.

As indicated in **Attachment G**, the maximum concentration of Total PCBs in surface soil (sample PCBAREA1-013) is 610 mg/kg under the Detects Only method and 621.7 m/kg under the Full DL method. This sample also exhibits the maximum difference between the two methods of 11.7 mg/kg. The average difference between the methods for surface soil is less than 1 mg/kg. Given the range of the Total PCB concentrations in surface soil, the calculation methodology does not significantly alter the findings of the HHRA that Total PCBs are a risk driver in Soil Exposure Area 2 surface soil.

As indicated in **Attachment G**, the maximum concentration of Total PCBs in subsurface soil (sample PCBAREA1-202) is 83 mg/kg under the Detects Only method and 88.1 m/kg under the Full DL method. This sample also exhibits the maximum difference between the two methods of 5.1 mg/kg. The average difference between the methods for surface soil is less than 0.5 mg/kg. Given the range of the Total PCB concentrations in subsurface soil, the calculation methodology

does not significantly alter the findings of the HHRA that Total PCBs are a risk driver in Soil Exposure Area 2 subsurface soil.

PCBs were not detected in groundwater. Therefore, the calculation method makes no difference in the results of the HHRA. PCBs were detected in one surface water sample, FTA-SW-06, collected in 2014. The Total PCB concentration under the Full DL method of 0.76 µg/L is greater than the Total PCB concentration of 0.38 µg/L under the Detects Only method. However, given the low risks identified in surface water, the difference in calculation methodology does not significantly alter the findings of the HHRA that Total PCBs are not a risk driver in surface water.

The differences in the Total PCB concentrations in sediment are small (maximum difference of 0.262 mg/kg in a sample from location FTA-SED-06 from 2012) and do not change the findings of the HHRA that Total PCBs are not a risk driver in sediment.

In summary, while using the Full DL method increases the Total PCB concentrations for some samples (i.e., those with non-detect PCB Aroclors), the increase is minimal and does not affect the conclusions of the HHRA.

4.7.3 COPC Selection

A comparison of maximum detected chemical concentrations to USEPA RSLs and other screening values was conducted as part of the COPC selection process. RSLs are conservative risk-based values that are used when selecting COPCs so as not to omit a chemical that might contribute significantly to risk. Chemicals whose maximum concentrations were below their respective screening value were not identified as COPCs or carried through the Tier II HHRA. It is unlikely that this risk-based screening excluded chemicals that would be of concern, based on the conservative exposure assumptions and conservatively derived toxicity criteria that are the basis of the screening level. Although following this methodology does not provide a quantitative risk estimate for all chemicals, it focuses the assessment on the chemicals accounting for the greatest risks (i.e., chemicals whose maximum concentrations exceeded their respective screening level). Although the overall potential risk estimates are uncertain, it is not expected that actual risks will be significantly greater than estimated risks given that a reasonable effort was made to characterize current and future potential health risks given current knowledge.

4.7.4 Toxicological Data

Uncertainty is associated with the toxicity values and toxicity information available to assess potential adverse effects.

One of the major contributors to uncertainty is the accuracy of the toxicity values used. A cancer potency value is a mathematical extrapolation of the slope of the dose-response curve from high doses administered to animals (or the exposures observed in epidemiological studies) to the low

doses commonly experienced in the environment. The USEPA has developed potency values for chemicals classified as carcinogens, based on the premise that there is no threshold (i.e., there is no level of exposure below which there is no risk of a carcinogenic effect). USEPA's *Guidelines for Carcinogen Risk Assessment* (USEPA 2005a) acknowledges that the mode of action of a carcinogen may involve both threshold and non-threshold mechanisms. To the extent that the approach used to develop the potency estimate is incorrect, the extrapolated risks may be overestimations or underestimations. However, in the derivation of toxicity values, conservative assumptions are employed. Therefore, toxicity values tend to be biased toward overestimating potential risk.

For dermal exposure pathways, the absence of dermal toxicity criteria necessitated the use of oral toxicity data. To calculate potential risk estimates for the dermal pathway, absolute oral bioavailability factors that reflect the toxicity study conditions were used to modify the oral toxicity criteria. For the chemicals with oral absorption exceeding 50%, a default oral absorption factor of 100% was used. The potential risk estimates for the dermal pathways may be overestimated or underestimated depending on how closely these values reflect the difference between the oral and dermal routes. Dermal absorption fractions (USEPA 2004a), which estimate the penetration of soil-associated chemicals through the skin, are used to assess dermal exposures for soil. These estimates are uncertain and may result in either an overestimation or underestimation of risk.

Chronic toxicity values, developed based on continuous lifetime exposures, were used for the evaluation of discontinuous, less-than-lifetime exposures (e.g., recreational user). Therefore, total receptor risk estimates may be overestimated with the degree of overestimation dependent on the degree of deviation from a continuous lifetime exposure scenario.

Total PCBs

Cancer toxicity values for Total PCBs (high risk and persistence) recommended in USEPA's IRIS database (2016i) were used for evaluation of Total PCBs. A published noncancer toxicity value (RfD) is not available for Total PCBs. Therefore, the oral RfD for PCB Aroclor-1254 (USEPA 2016i) was used to evaluate noncarcinogenic oral/dermal pathways associated with exposure to Total PCBs. PCB Aroclor-1254 was detected in site media. However, there are uncertainties associated with using PCB Aroclor-1254 as a surrogate for Total PCBs. Since the PCB composition at a site may differ from the PCB composition for which the noncancer RfD for PCB Aroclor-1254 is based, producing different toxicological responses, uncertainty is introduced by using this as a surrogate RfD. During the Feasibility Study, the uncertainties associated with using the noncancer RfD for PCB Aroclor-1254 as a surrogate for Total PCBs to develop the preliminary remediation goal (PRG) based on a noncancer endpoint will be considered, in order to select an appropriate PRG for use at the site as part of a risk management decision.

4.7.5 Exposure Assessment

The primary areas of uncertainty affecting exposure parameter estimation involve the assumptions regarding exposure pathways, the estimation of EPCs, and the parameters used to estimate chemical doses. The uncertainties associated with these various sources are discussed in the following sections.

4.7.5.1 EPCs

With respect to determining EPCs for this evaluation, one assumption was that the concentrations of chemicals in the medium evaluated would remain constant over the exposure time. Depending on the properties of the chemical and the medium in which it was detected, this assumption may overestimate risks, depending on the degree of chemical degradation to less toxic species or transport to other media. Conversely, environmental bioactivation of chemicals to more toxic chemicals was also not considered. Therefore, this assumption may underestimate risk if bioactivation mechanisms are significant.

EPCs for soil, sediment, and surface water were calculated based on available data in each exposure area. Groundwater EPCs were calculated following USEPA guidance (2014b) and were based groundwater data collected since 2014 from permanent monitoring wells. EPCs are expected to be conservative because in reality, samples were not collected based on random sampling but rather based on knowledge of historical practices and locations where the highest concentrations were expected. Therefore, EPCs are likely to be biased high.

Future development could result in mixing of surface soil and subsurface soil, or removal of surface soil, resulting in subsurface soil being exposed as surface soil. It is also possible that grading activities would add soil or other fill to the surface, such that current surface soils would be covered. Given the uncertainties involved with anticipating future conditions, separate EPCs were derived for surface soil and subsurface soil. This approach could over-or underestimate future EPCs depending on redevelopment activities, but allows for risk management decisions based on current conditions.

EPCs for shower air, indoor air via the vapor intrusion pathway, and excavation trench air were estimated through use of modeling, which introduces some level of uncertainty, as discussed in the following paragraphs.

There are uncertainties associated with estimating shower air EPCs from groundwater using the Foster and Chrostowski (1987) shower model. Activity parameters that have uncertainty associated with them include shower durations and time spent in the room after a shower. Measurement uncertainty is associated with some input parameters used in the model (e.g., droplet size) and the experimental data used to validate the model. Although the main source of VOCs in shower air is expected to be the shower spray itself, the conceptualization of the model as falling droplets only

may result in an underestimation of modeled indoor concentrations (Foster and Chrostowski 2003). The model also makes several conservative assumptions such as assuming exposure time equals duration of shower use and not accounting for the actual decrease in concentration after the water is turned off. Therefore, when all of the exposure and modeling assumptions are combined, it is much more likely that potential risks are significantly overestimated rather than underestimated.

Indoor air EPCs were estimated via indoor air modeling using the USEPA JE model spreadsheets (USEPA 2004b; 2004c). The use of modeling to estimate indoor air concentrations for hypothetical buildings contributes uncertainty to the HHRA. In addition, the vapor intrusion evaluation performed as part of this HHRA based on the use of measured groundwater data does not account for potential sources of volatiles in the unsaturated zone (i.e., in soils above the water table). Therefore, if future development of the site is planned, further evaluation of the potential vapor intrusion pathway may be considered in the area of proposed buildings.

4.7.5.2 Exposure Assumptions

The parameter values used to describe the extent, frequency, and duration of exposure are associated with some uncertainty. Actual risks for some individuals within an exposed population may vary from those predicted depending on the actual exposure durations, intake rates (e.g., soil ingestion rates), or body weights.

The FTA is currently an unused and undeveloped open space, and this use is expected to continue for the foreseeable future. Therefore, under the current scenario, only potential trespassers and construction workers are evaluated. While there are no plans for future site use, several future scenarios are evaluated in order to aid in risk-management decisions, including recreational use, industrial use, and hypothetical residential use. Because most of the exposure scenarios are hypothetical, several conservative exposure assumptions were used in the HHRA consistent with MEDEP's recommended default exposure assumptions (MEDEP/CDC 2013), as discussed further here.

The construction worker exposure scenario evaluated in the HHRA was conservatively based on recommended exposure assumptions provided MEDEP/CDC. This scenario conservatively assumed that construction workers may be working full time for a 1 year period on site and are potentially exposed to soil for 250 days per year (5 days per week for a 1-year project). However, a more typical exposure scenario for a construction worker is likely to be less than what was assumed. It was also conservatively assumed that a construction worker at the FTA may contact groundwater in an excavation trench and surface water and sediment in the wetland area, assuming he/she may be performing excavation/regrading activities along the wetland. These are also conservative assumptions given that construction workers are likely to be wearing protective clothing to reduce

their contact with site media. Therefore, it is likely that use of these default exposure assumptions may overestimate potential risk to current/future construction workers at the FTA.

Consistent with MEDEP's recommended exposure assumptions (MEDEP/CDC 2013), it was conservatively assumed that the adult and child recreational users engage in activities resulting in soil exposure 90 days per year (3 days per week for 30 weeks [the 7 warmer months] of the year). However, it is unlikely that recreational users would spend 3 days per week for 6 to 7 months of the year at the site, and therefore, use of MEDEP's recommended exposure assumptions are likely to overestimate potential risk associated with a typical recreational exposure scenario.

In addition, consistent with MEDEP's recommended exposure assumptions (MEDEP/CDC 2013), ingestion rates and adherence factors for soil were used for evaluation of sediment exposure. There is some uncertainty associated with this since actual contact with each media may be different (e.g., using the soil adherence factor to evaluate sediment exposure when actual adherence may differ depending on percent moisture content). The fraction of soil and sediment ingested from the site were each assumed to be 100%. MEDEP/CDC's recommended exposure assumptions (2013) assume the ingestion rates for sediment are equal to those for soil. Because the default soil ingestion rates represent the total daily intake of soil integrated over a variety of activities and sources, both indoors and outdoors, the assumption of 100% fraction ingested for both soil and sediment is very conservative. The combination of these assumptions results in a combined soil and sediment ingestion rate twice the daily assumed soil ingestion rate for each receptor assumed to be exposed to both soil and sediment (current/future construction worker, current/future recreational user, hypothetical future on-site resident).

The exposure assumptions were generally selected to produce a reasonable upper-bound estimate of exposure in accordance with USEPA guidelines, although in some cases the combination of the various assumptions may lead to greater than an upper bound estimate. Therefore, exposures and estimated potential risks for the evaluated receptors are likely to be representative of reasonable upper-bound exposures, but in some cases may exceed reasonable upper-bound exposures.

Geological material at FTA is dominated by local fill material consisting of cobbles, gravel, course sand, and silt over most of the site. The default soil contact assumptions used in the HHRA (e.g., soil adherence factors) are considered to overestimate exposure for contact with cobbles and gravel.

4.7.5.3 Dermal Absorption from Groundwater and Surface Water

Potential noncancer hazards for PAHs, PCBs, PFOS, and PFOA were estimated based on ingestion of groundwater and incidental ingestion of surface water as applicable for the receptors evaluated. The dermal contact pathway associated with these COPCs in water is considered to be negligible,

as further discussed in the following paragraphs, and was therefore not quantitatively evaluated in the HHRA.

In dermal exposure assessment (USEPA 2007), the potential dermal dose is the amount of a chemical which could be deposited on the skin during a given activity. The absorbed dermal dose is the amount of a chemical that is absorbed into the body through the skin. Passive diffusion is considered to be the main processes of dermal penetration of chemicals through the stratum corneum, the outermost layer of the skin. After a chemical has absorbed into the stratum corneum it can pass through it into the viable epidermis (the next skin layer) and then into the dermis where it can be transported systemically by the dermal blood supply. To get into and through the skin, the chemical must dissolve into the stratum corneum, a stabilized lipid barrier. Hence, lipid solubility is required initially, followed by water solubility, to pass through the water-based gel portion of the skin and the human body, which is water-based. The dermal permeability coefficient (K_p) indicates the rate of migration of a chemical through skin and may be a predicted or experimentally derived value (USEPA 2004a). USEPA uses the K_p value (in units of centimeters per hour) to evaluate dermal exposure to chemicals in water, such as surface water.

The quantification of potential noncancer hazards and cancer risks associated with the surface water pathway followed Exhibit 1-2 in the USEPA RAGS Part E guidance (2004a). Specifically, if dermal assessment was not recommended in USEPA RAGS Part E (2004a), no further evaluation of the dermal pathway was conducted for that COPC. Dermal assessment is not recommended for chemicals with a very large or very small octanol-water partition coefficient value. These chemicals are considered to be outside of the "Effective Prediction Domain," which means that an appropriate K_p value cannot be predicted by the statistical model (USEPA 2004a).

Specifically for PFOA and PFOS, evidence of dermal absorption of was documented in experimental studies; however, the findings of two key dermal exposure studies suggest that the ionization state of PFOA is critical in understanding its dermal absorption and permeability potential. At normal stratum corneum pH, PFOA is largely ionized and very little penetration of human skin would be expected to occur (Franko et al. 2012). Franko et al. (2012) also notes that most real-world PFOA exposures, particularly very low-level environmental exposures, would be to the ionized form and not the unionized form, suggesting dermal absorption through human skin under typical environmental exposures would be likely negligible relative to the oral exposure route.

Considering the pH-dependent dermal permeability data for PFOA, exclusion of the evaluation of the dermal route for PFOS and PFOA in water in a HHRA is not likely to result in significant underestimation of the overall human health risk to PFOS and PFOA at a site. Similarly, significant underestimation of human health risk is not expected if the evaluation of the dermal route for

PFOS and PFOA in sediments is excluded from an HHRA because exposure via the oral route is considered to drive overall potential health risk.

The HHRA utilizes the total (unfiltered) groundwater data for oral exposure pathways, consistent with the recommendation in USEPA (2004a). However, as indicated in USEPA (2004a):

> "…particulate-bound chemicals in an aqueous medium (e.g., suspended sediment particles) would be considered to be much less bioavailable for dermal absorption, due to inefficient adsorption of suspended particles onto the skin surface and a slower rate of absorption into the skin….The actual bioavailable concentration is likely to lie somewhere between the unfiltered and filtered sample concentrations."

Therefore, the use of the unfiltered data for the dermal contact pathway is conservative.

Based on currently available scientific data and information and consistent with USEPA guidance (2004a), quantitative estimation of dermal risk was not included in this HHRA for PFOS, PFOA, PCBs, and PAHs. While this process removes evaluation of analytes which contribute minimally to the dermal pathway, inclusion of quantitative estimates of potential risk associated with the dermal exposure route is not considered to change the conclusions of this HHRA.

4.8 Summary and Conclusions

An overall summary of potential ELCR and HI results for the receptors evaluated at the FTA is presented in **Tables 11.1.RME/CTE** through **11.5.RME/CTE**. A summary of the HHRA conclusions, including a summary of the risk drivers not attributable to background media, is presented as follows by receptor.

4.8.1 Current/Future Construction Worker

A current/future construction worker was evaluated for exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air; groundwater through incidental ingestion, dermal contact and inhalation of volatiles in an excavation trench; and exposure to surface water and sediment in the wetland area through incidental ingestion and dermal contact. Potential soil exposure scenarios were evaluated on an exposure area basis. Potential groundwater exposure scenarios were evaluated based on EPCs developed for wells with the highest concentrations. The wetland was evaluated as one exposure area for both surface water and sediment.

All total ELCRs for the RME and CTE current/future construction worker are within USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Therefore, no risk drivers are identified based on potential carcinogenic risk utilizing USEPA guidance or MEDEP guidance.

Target organ HIs are greater than MEDEP's and/or USEPA and MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- Soil Exposure Area 1
  - *Surface Soil:* Manganese (RME and CTE)
  - *Subsurface Soil:* Manganese (RME and CTE)
- Soil Exposure Area 2
  - *Surface Soil:* Manganese (RME), Total PCBs (RME only)
  - *Subsurface Soil:* Manganese (RME and CTE)

Figure 4-3 of the RI report presents PCB Aroclor-1260 concentrations in soil, and Figure 4-4 of the RI report presents manganese concentrations in soil.

4.8.2 Current/Future On-Site Recreational User/Trespasser

A current/future on-site recreational user (adult/child) was evaluated for exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air; and exposure to surface water and sediment in the wetland area through incidental ingestion and dermal contact. Potential soil exposure was evaluated on an exposure area basis.

The total ELCRs for the RME and CTE current/future recreational user/trespasser are within USEPA's target ELCR range of 10^{-6} to 10^{-4}. Therefore, no risk drivers are identified based on potential carcinogenic risk utilizing USEPA guidance.

Total ELCRs/HIs are above MEDEP's target ELCR of 10^{-5} and/or USEPA and MEDEP's target HI of 1 within the following exposure areas and media based on the following risk drivers:

- Soil Exposure Area 2
  - *Surface Soil:* Total PCBs (RME and CTE) and benzo(a)pyrene (RME only)

Figure 4-3 of the RI report presents PCB Aroclor-1260 concentrations in soil.

4.8.3 Future Outdoor Industrial Worker

A future outdoor industrial worker was evaluated for exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air on an exposure area basis.

The total ELCRs for the RME and CTE future outdoor industrial worker are below or within USEPA's target ELCR range of 10^{-6} to 10^{-4}. Therefore, no risk drivers are identified based on potential carcinogenic risk utilizing USEPA guidance.

Total ELCRs/HIs are above MEDEP's target ELCR of 10^{-5} and/or USEPA and MEDEP's target HI of 1 within the following exposure areas and media based on the following risk drivers:

- Soil Exposure Area 2
  - *Surface Soil:* Total PCBs (RME only)

Figure 4-3 of the RI report presents PCB Aroclor-1260 concentrations in soil.

4.8.4 Future Indoor Industrial Worker

A future indoor industrial worker was evaluated for exposure to volatiles in groundwater via the vapor intrusion pathway. Potential exposure for this scenario was evaluated assuming a commercial/industrial building may be constructed anywhere on site under a hypothetical future use scenario.

The total potential ELCRs for the RME and CTE future indoor industrial worker are below USEPA's target ELCR range of 10^{-6} to 10^{-4} and below MEDEP's target ELCR of 10^{-5}. Total potential HIs are below USEPA/MEDEP's target HI of 1. Therefore, no risk drivers are identified for the future indoor industrial worker.

4.8.5 Hypothetical Future On-Site Resident

A hypothetical future on-site resident was evaluated for exposure to surface soil and subsurface soil through incidental ingestion, dermal contact, and inhalation of airborne particles (i.e., fugitive dust) in outdoor air; exposure to volatiles in groundwater via showering or bathing and in indoor air via the vapor intrusion pathway; and exposure to surface water and sediment in the wetland area through incidental ingestion and dermal contact. Potential soil exposure scenarios were evaluated on an exposure area basis. Potential groundwater exposure scenarios were evaluated based on EPCs developed for wells with the highest concentrations. The wetland was evaluated as one exposure area for both surface water and sediment. It is assumed that a residence may be constructed anywhere on site and/or a private potable well may be installed for residential use anywhere on site under a hypothetical future use scenario.

Total ELCRs are above MEDEP's target ELCR of 10^{-5} and/or above USEPA/MEDEP's target HI of 1 within the following exposure areas and media based on the following chemicals:

- Soil Exposure Area 2
  - *Surface Soil:* Total PCBs (RME and CTE), benzo(a)pyrene (RME only)
  - *Subsurface Soil:* Total PCBs and arsenic (RME only)
- Groundwater
  - Trichloroethene, arsenic, and manganese (RME and CTE); vinyl chloride (RME only)

Figure 4-3 of the RI report presents PCB Aroclor-1260 concentrations in soil.

4.8.6 Risk Driver Summary

Based on the evaluation for each receptor and the results of the background evaluation, the following have been identified as a risk driver not attributable to background for one or more receptor scenarios:

- Total PCBs
  - Soil Exposure Area 2 surface soil
  - Soil Exposure Area 2 subsurface soil
- Benzo(a)pyrene
  - Soil Exposure Area 2 surface soil
- Arsenic
  - Soil Exposure Area 2 subsurface soil only
  - Groundwater
- Manganese:
  - Soil Exposure Area 1 surface soil
  - Soil Exposure Area 1 subsurface soil
  - Soil Exposure Area 2 surface soil
  - Soil Exposure Area 2 subsurface soil
  - Groundwater
- Trichloroethene
  - Groundwater
- Vinyl Chloride
  - Groundwater

Notes:
● Potentially complete pathway.
○ Pathway considered to be incomplete or insignificant.
ft bgs - feet below ground surface.
(a) It is assumed that future development may bring subsurface soils to the surface, making it available for contact by these receptors.
(b) Represents exposure to air within an open excavation trench containing standing water (i.e., trench air).
(c) Asssumes potential inhalation exposure to volatiles may occur via the vapor intrusion pathway.
(d) Assumes potential exposure may occur while showering/bathing.

HHRA - Human Health Risk Assessment.

FTA - Fire Training Area.

Surface soils are defined as soils collected between 0 and 2 feet below ground surface (ft bgs); Subsurface soils are defined as soils collected deeper than 2 ft bgs, to a maximum depth of 15 ft bgs. One soil sample collected from 1 to 3 ft bgs was included in the subsurface soil dataset.

(a) Evaluated for the following exposure areas: Area 1, Area 2. These areas are described in the HHRA report text.

TABLE 2.1
OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN - SOIL EXPOSURE AREA 1
HUMAN HEALTH RISK ASSESSMENT
FIRE TRAINING AREA, NCTAMS LANT DET CUTLER
CUTLER, MAINE

Scenario Timeframe: Current/Future
Medium: Soil
Exposure Medium: Surface/Subsurface Soil

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Background Value (4)	Screening Toxicity Value (NC/C) (5)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	COPC Flag (Y/N)	Rationale for Selection or Deletion (6)

TABLE 2.1
OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN - SOIL EXPOSURE AREA 1
HUMAN HEALTH RISK ASSESSMENT
FIRE TRAINING AREA, NCTAMS LANT DET CUTLER
CUTLER, MAINE

Scenario Timeframe:	Current/Future
Medium:	Soil
Exposure Medium:	Surface/Subsurface Soil

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Background Value (4)	Screening Toxicity Value (NC/C) (5)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	COPC Flag (Y/N)	Rationale for Selection or Deletion (6)

Notes:

Refer to Attachment A for samples included in data set.

Surface soil is defined as soil samples collected from 0 to 2 ft bgs.

Subsurface soil is defined as soil samples collected at depths greater than 2 ft bgs, to a maximum depth of 15 ft bgs. One sample collected from 1 to 3 ft bgs is included as subsurface soil.

Totals for use in risk assessment are calculated as discussed in the report text and have a CAS number beginning with "RA-".

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

ft bgs - feet below ground surface.

L = Lead screening level developed by USEPA using blood-lead modeling based on target blood lead concentrations (USEPA Regional Screening Level (RSL) Table User's Guide.

mg/kg - milligrams per kilogram.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

B = For organics, the analyte was found in the associated blank at a significant level relative to the sample result.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening, except for lead for which the mean detected concentration is used.

(4) Background values were not used for COPC screening purposes, although applicable background values may be considered in the risk characterization portion of the risk assessment, if available.

(5) Screening levels are equal to the USEPA Regional Screening Level (RSL) for residential soil based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2016).

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for cadmium in the diet was used for cadmium.

The value for endrin was used for endrin ketone.

The value for trivalent chromium was used for total chromium.

The value for Aroclor 1254 was used for Total Aroclors.

The value for manganese non-diet was used for manganese.

The value for anthracene was used for phenanthrene.

The value for mercuric chloride was used for mercury.

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

TABLE 2.2

OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN - SOIL EXPOSURE AREA 2

HUMAN HEALTH RISK ASSESSMENT

FIRE TRAINING AREA, NCTAMS LANT DET CUTLER

CUTLER, MAINE

Scenario Timeframe:	Current/Future
Medium:	Soil
Exposure Medium:	Surface/Subsurface Soil

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Background Value (4)	Screening Toxicity Value (NC/C) (5)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	COPC Flag (Y/N)	Rationale for Selection or Deletion (6)

Notes:

Refer to Attachment A for samples included in data set.

Surface soil is defined as soil samples collected from 0 to 2 ft bgs.

Subsurface soil is defined as soil samples collected at depths greater than 2 ft bgs, to a maximum depth of 15 ft bgs. One sample collected from 1 to 3 ft bgs is included as subsurface soil.

Totals for use in risk assessment are calculated as discussed in the report text and have a CAS number beginning with "RA-".

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

EPHs = Extractable Petroleum Hydrocarbons.

ft bgs - feet below ground surface.

L = Lead screening level developed by USEPA using blood-lead modeling based on target blood lead concentrations (USEPA Regional Screening Level (RSL) Table User's Guide.

mg/kg - milligrams per kilogram.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

B = For organics, the analyte was found in the associated blank at a significant level relative to the sample result.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening, except for lead for which the mean detected concentration is used.

(4) Background values were not used for COPC screening purposes, although applicable background values may be considered in the risk characterization portion of the risk assessment, if available.

(5) Screening levels are equal to the USEPA Regional Screening Level (RSL) for residential soil based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2016).

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for cadmium in the diet was used for cadmium.

The value for trivalent chromium was used for total chromium.

The value for manganese non-diet was used for manganese.

The value for mercuric chloride was used for mercury.

The value for endrin was used for endrin aldehyde and endrin ketone.

The value for endosulfan was used for endosulfan I, endosulfan II, and endosulfan sulfate.

The value for Aroclor 1254 was used for Total Aroclors.

The value for 1,4-dichlorobenzene was used for 1,3-dichlorobenzene.

The value for anthracene was used for phenanthrene.

The value for fluorene was used for carbazole.

The value for pyrene was used for benzo(g,h,i)perylene.

The value for toluene was used for methylcyclohexane.

The value for xylenes was used for m- and p-xylene

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

Notes:

Refer to Attachment A for samples included in data set.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.
Totals for use in risk assessment are calculated as discussed in the report text and have a CAS number beginning with "RA-".

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

EN = Essential nutrient.

ft = Feet.

ug/L - micrograms per liter.

MCL - Maximum Contaminant Level.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

NV = Not volatile.

PFAS = Poly- and Perfluoroalkyl Substances.

PFOS = Perfluorooctanesulfonic acid or Perfluorooctane sulfonate

PFOA = Perfluorooctanoic acid.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) Background values were not used for COPC screening purposes, although applicable background values may be considered in the risk characterization portion of the risk assessment, if available.

(5) Groundwater screening levels include the following:

- USEPA Maximum Contaminant Levels (MCLs) for drinking water. Accessed October 2016. https://www.epa.gov/ground-water-and-drinking-water/table-regulated-drinking-water-contaminants.

- USEPA Regional Screening Level (RSL) for tapwater based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2016).

Values calculated for PFOA and PFOS using the USEPA Regional Screening Level (RSL) Calculator (May 2016 version). Default exposure assumptions provided by USEPA in the calculator were used unless noted otherwise. Target cancer risk of 1x10-6 and a target hazard quotient of 0.1 used to account for cumulative effects on the same target organ. USEPA's chronic RfD for PFOS and PFOA (2x10-5 mg/kg-day) published in the following documents in May 2016: "Drinking Water Health Advisory for Perfluorooctane Sulfonate (PFOS)" and "Drinking Water Health Advisory for Perfluorooctanoic Acid (PFOA)". [EPA 822-R-16-004] were used.

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for cadmium in water was used for cadmium.

The value for trivalent chromium was used for total chromium.

The value for manganese non-diet was used for manganese.

The value for anthracene was used for phenanthrene.

- USEPA Vapor Intrusion Screening Level (VISL) for groundwater based on a residential exposure scenario, a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens (May 2016).

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL) - MCL and/or RSL and/or VISL

Deletion Reason: Below Screening Levels (BSL); Essential Nutrient (NUT)

TABLE 2.4
OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN - WETLAND SURFACE WATER
HUMAN HEALTH RISK ASSESSMENT
FIRE TRAINING AREA, NCTAMS LANT DET CUTLER
CUTLER, MAINE

Notes:

Refer to Attachment A for samples included in data set.

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

Totals for use in risk assessment are calculated as discussed in the report text and have a CAS number beginning with "RA-".

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

EN = Essential Nutrient.

MEDEP = Maine Department of Environmental Protection.

ug/L - micrograms per liter.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) Background values were not used for COPC screening purposes, although applicable background values may be considered in the risk characterization portion of the risk assessment, if available.

(5) Surface water screening levels include the following:

- USEPA National Recommended Water Quality Criteria for Priority Pollutants. Value for Human Health for the consumption of water and organisms. 2015.

  Value for lead is equal to the USEPA Action Level for lead in water. http://water.epa.gov/drink/contaminants/index.cfm.

- MEDEP Surface Water Quality Criteria for human health consumption of water and organisms. 2012.

- Risk-based screening levels for surface water calculated using the USEPA Regional Screening Level (RSL) Calculator (May 2016) for a recreator adult/child scenario, based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens, using the following exposure assumptions protective of site-specific exposures:

  Exposure Frequency (days/year) = 78

  Exposure Duration (years) = Adult - 20; Child - 6

  Exposure Time (hour/day) = 2.6

  Body Weight (kg) = Adult - 80; Child - 15

  Skin Surface Area (cm^2/day) = Adult - 7,535; Child - 2,373

  Ingestion Rate (L/hour) = Adult - 0.01; Child - 0.05

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for cadmium in water was used for cadmium.

The value for anthracene was used for phenanthrene.

The value for PCBs (low risk) was used for Total Aroclors.

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

TABLE 2.5
OCCURRENCE, DISTRIBUTION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN - WETLAND SEDIMENT
HUMAN HEALTH RISK ASSESSMENT
FIRE TRAINING AREA, NCTAMS LANT DET CUTLER
CUTLER, MAINE

Scenario Timeframe:	Current/Future
Medium:	Sediment
Exposure Medium:	Sediment

Exposure Point	CAS Number	Chemical	Minimum Concentration (Qualifier) (1)	Maximum Concentration (Qualifier) (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits (2)	Concentration Used for Screening (3)	Background Value (4)	Screening Toxicity Value (NC/C) (5)	Potential ARAR/TBC Value	Potential ARAR/TBC Source	COPC Flag (Y/N)	Rationale for Selection or Deletion (6)

Notes:

Refer to Attachment A for samples included in data set.

Totals for use in risk assessment are calculated as discussed in the report text and have a CAS number beginning with "RA-".

ARAR/TBC = Applicable or Relevant and Appropriate Requirements/To be Considered.

C = Cancer. Screening value is based on the screening level protective of carcinogenic effects.

CAS = Chemical Abstracts Service.

COPC = Chemical of Potential Concern.

EN = Essential Nutrient.

L = Lead screening level developed by USEPA using blood-lead modeling based on target blood lead concentrations (USEPA Regional Screening Level (RSL) Table User's Guide.

ft = Feet.

mg/kg - milligrams per kilogram.

N/A = Not Applicable or Not Available.

NC = Noncancer. Screening value is based on the screening level protective of noncarcinogenic effects.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Minimum/maximum detected concentration and associated data flags.

J = The chemical was positively identified; however, the associated numerical value is an estimated concentration.

(2) Lab Reporting Detection Limits (RDLs) are shown where the frequency of detection is less than 100%.

(3) Maximum detected concentration used for screening.

(4) Background values were not used for COPC screening purposes, although applicable background values may be considered in the risk characterization portion of the risk assessment, if available.

(5) Risk-based screening levels for sediment are calculated using the USEPA Regional Screening Level (RSL) Calculator (May 2016) for a recreator adult/child scenario, based on a target risk level of 1x10-6 for carcinogens and a target hazard quotient of 0.1 for noncarcinogens, using the following exposure assumptions protective of site-specific exposures:

Exposure Frequency (days/year) = 78

Exposure Duration (years) = Adult - 20; Child - 6

Exposure Time (hour/event) = 0 (used for inhalation pathway only, which is not applicable for sediment exposure)

Body Weight (kg) = Adult - 80; Child - 15

Skin Surface Area (cm^2/day) = Adult - 7,535; Child - 2,373

Adherence Factor (mg/cm^2) = Adult - 0.3; Child - 0.2

Ingestion Rate (mg/day) = Adult - 100; Child - 200

The following surrogates were used for chemicals without available screening levels or with multiple forms:

The value for phenol was used for 3- and 4-methylphenol.

The value for pyrene was used for benzo(g,h,i)perylene.

The value for cadmium in the diet was used for cadmium.

The value for fluorene was used for carbazole.

The value for endosulfan was used for endosulfan I, endosulfan II and endosulfan sulfate.

The value for endrin was used for endrin aldehyde and endrin ketone.

The value for mercuric chloride was used for mercury.

The value for anthracene was used for phenanthrene.

The value for PCBs (high risk) was used for Total Aroclors.

The value for toluene was used for methylcyclohexane.

The value for trivalent chromium was used for total chromium.

(6) Rationale Codes:

Selection Reason: Above Screening Level (ASL)

Deletion Reason: Below Screening Level (BSL); Essential Nutrient (NUT)

Total:		**9**	**8**	**17**	**10**	**14**	**9**	**10**

Notes:

CAS = Chemical Abstracts Service.
COPC = Chemical of Potential Concern.
PCBs = Polychlorinated biphenyls
PFASs = Poly- and Perfluoroalkyl Substances.
PFOS - Perfluorooctanesulfonic acid (Perfluorooctane sulfonate).
PFOA = Perfluorooctanoic acid.
SVOCs = Semivolatile organic compounds.
VOCs = Volatile organic compounds.

Surface soil is defined as soil samples collected from 0 to 2 ft bgs.
Subsurface soil is defined as soil samples collected at depths greater than 2 ft bgs, to a maximum depth of 15 ft bgs.
X = Indicates the chemical is a COPC for the associated receptor.
(a) COPC for groundwater direct-contact pathways.
(b) COPC for groundwater direct-contact pathways, shower air, and trench air pathways.
(c) COPC for groundwater direct-contact pathways, indoor air, shower air, and trench air pathways.

TABLE 3.1.RME
EXPOSURE POINT CONCENTRATION SUMMARY - SOIL
REASONABLE MAXIMUM EXPOSURE
HUMAN HEALTH RISK ASSESSMENT
FIRE TRAINING AREA, NCTAMS LANT DET CUTLER
CUTLER, MAINE

Scenario Timeframe:	Current/Future
Medium:	Soil
Exposure Medium:	Surface/Subsurface Soil

Exposure Point	Chemical of Potential Concern	CAS Number	Units	Frequency of Detection	Arithmetic Mean (1)	UCL (Distribution) (2)	Maximum Concentration (Qualifier) (3)	Exposure Point Concentration			
								Value	Units	Statistic (4)	Rationale (5)

Notes:

CAS = Chemical Abstracts Service.

EPC = Exposure point concentration.

mg/kg = milligrams per kilogram.

RME = Reasonable Maximum Exposure.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

UCL = Upper confidence limit.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Arithmetic means were calculated using detected concentrations only.

(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.00. For data sets with multiple detection limits for non-detects, the use of the Kaplan-Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan-Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.
N = Normal; LN = Lognormal; G = Gamma; ND = Not Discernable; NC = Not calculated.

(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.

(4) Indicates the statistic on which the exposure point concentration is based.
Average Concentration = Arithmetic Mean detected concentration.
Maximum Concentration = Maximum detected concentration.
95% Student's-t UCL = Calculated using a normal Student's t approximation procedure.
95% Modified-t UCL = Calculated using a modified t approximation procedure.
95% Adjusted Gamma UCL = Calculated using Adjusted Gamma distribution procedure.
95% Adjusted Gamma KM-UCL = Calculated using Kaplan-Meier Adjusted Gamma distribution procedure.
95% Chebyshev (Mean, Sd) UCL = Calculated using Chebyshev inequality non-parametric procedure.
95% KM (t) UCL = Calculated using 95% Kaplan-Meier (Student's t approximation) non-parametric procedure.
95% KM (Chebyshev) UCL = Calculated using 95% Kaplan-Meier (Chebyshev inequality) non-parametric procedure.
97.5% KM (Chebyshev) UCL = Calculated using 97.5% Kaplan-Meier (Chebyshev inequality) non-parametric procedure.
95% H-UCL (KM -Log) = UCL based upon Land's H-statistic, KM mean andsd on logged data.

(5) The UCL recommended by ProUCL is used (where mulitple values are recommended, the higher is used), unless otherwise noted, as below.
(a) Maximum detected concentration used for EPC due to the low number of detections (less than 6) or small sample size (less than 10).
(b) ProUCL recommended two UCLs. Because the bootstrap method UCL exceeds the max, the adjusted gamma UCL has been used, consistent with the technical guidance.

CUTLER, MAINE

Scenario Timeframe:	Current/Future
Medium:	Soil
Exposure Medium:	Surface/Subsurface Soil

Exposure Point	Chemical of Potential Concern	CAS Number	Units	Frequency of Detection	Arithmetic Mean (1)	UCL (Distribution) (2)	Maximum Concentration (Qualifier) (3)	Exposure Point Concentration			
								Value	Units	Statistic (4)	Rationale (5)

Notes:

CAS = Chemical Abstracts Service.

CTE = Central Tendency Exposure.

EPC = Exposure point concentration.

mg/kg = milligrams per kilogram.

RME = Reasonable Maximum Exposure.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

UCL = Upper confidence limit.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds.

(1) Arithmetic means were calculated using detected concentrations only.

(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.00. For data sets with multiple detection limits for non-detects, the use of the Kaplan-Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan-Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.
N = Normal; LN = Lognormal; G = Gamma; ND = Not Discernable; NC = Not calculated.

(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.

(4) Indicates the statistic on which the exposure point concentration is based.
Average Concentration = Arithmetic Mean detected concentration.
Maximum Concentration = Maximum detected concentration.
95% Student's-t UCL = Calculated using a normal Student's t approximation procedure.
95% Modified-t UCL = Calculated using a modified t approximation procedure.
95% Adjusted Gamma UCL = Calculated using Adjusted Gamma distribution procedure.
95% Adjusted Gamma KM-UCL = Calculated using Kaplan-Meier Adjusted Gamma distribution procedure.
95% Chebyshev (Mean, Sd) UCL = Calculated using Chebyshev inequality non-parametric procedure.
95% KM (t) UCL = Calculated using 95% Kaplan-Meier (Student's t approximation) non-parametric procedure.
95% KM (Chebyshev) UCL = Calculated using 95% Kaplan-Meier (Chebyshev inequality) non-parametric procedure.
97.5% KM (Chebyshev) UCL = Calculated using 97.5% Kaplan-Meier (Chebyshev inequality) non-parametric procedure.
95% H-UCL (KM -Log) = UCL based upon Land's H-statistic, KM mean andsd on logged data.

(5) The UCL recommended by ProUCL is used (where mulitple values are recommended, the higher is used), unless otherwise noted, as below.
(a) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CTE EPC.
(b) ProUCL recommended two UCLs. Because the bootstrap method UCL exceeds the mean, the adjusted gamma UCL has been used, consistent with the technical guidance.

N = Normal; LN = Lognormal; G = Gamma; ND = Not Discernable; NC = Not calculated.
(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.
(4) Indicates the statistic on which the exposure point concentration is based.
Maximum Concentration = Maximum detected concentration.
95% BCA Bootstrap UCL = Calculated using 95% bias-corrected procedure.
95% Student's-t UCL = Calculated using a normal Student's t approximation procedure.
95% Adjusted Gamma UCL = Calculated using Adjusted Gamma distribution procedure.
95% Adjusted Gamma KM-UCL = Calculated using Kaplan-Meier Adjusted Gamma distribution procedure.
95% KM (t) UCL = Calculated using 95% Kaplan-Meier (Student's t approximation) non-parametric procedure.
95% KM (Chebyshev) UCL = Calculated using 95% Kaplan-Meier (Chebyshev inequality) non-parametric procedure.
99% KM (Chebyshev) UCL = Calculated using 99% Kaplan-Meier (Chebyshev inequality) non-parametric procedure.
(5) The UCL recommended by ProUCL is used (where mulitple values are recommended, the higher is used).
(a) Maximum detected concentration used for EPC due to the low number of detections (less than 6) or small sample size (less than 10).

TABLE 3.2.CTE

EXPOSURE POINT CONCENTRATION SUMMARY - GROUNDWATER

CENTRAL TENDENCY EXPOSURE

HUMAN HEALTH RISK ASSESSMENT

FIRE TRAINING AREA, NCTAMS LANT DET CUTLER

CUTLER, MAINE

Scenario Timeframe:	Current/Future
Medium:	Groundwater
Exposure Medium:	Groundwater

Exposure Point	Chemical of Potential Concern	CAS Number	Units	Frequency of Detection	Arithmetic Mean (1)	UCL (Distribution) (2)	Maximum Concentration (Qualifier) (3)	Exposure Point Concentration			
								Value	Units	Statistic (4)	Rationale (5)

Notes:

CAS = Chemical Abstracts Service.

CTE = Central Tendency Exposure.

EPC = Exposure point concentration.

PFASs = Poly- and Perfluoroalkyl Substances.

PFOA = Perfluorooctanoic Acid.

PFOS - Perfluorooctanesulfonic acid (Perfluorooctane sulfonate).

RME = Reasonable Maximum Exposure.

SVOCs = Semivolatile organic compounds.

UCL = Upper confidence limit.

ug/L = Micrograms per liter.

USEPA = United States Environmental Protection Agency.

VOCs = Volatile organic compounds

(1) Arithmetic means were calculated using detected concentrations only.

(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.00. For data sets with multiple detection limits for non-detects, the use of the Kaplan-Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan-Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.
N = Normal; LN = Lognormal; G = Gamma; ND = Not Discernable; NC = Not calculated.

(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.

(4) Indicates the statistic on which the exposure point concentration is based.
Average Concentration = Arithmetic Mean detected concentration.
Maximum = Maximum detected concentration.
95% BCA Bootstrap UCL = Calculated using 95% bias-corrected non-parametric procedure.
95% Student's-t UCL = Calculated using a normal Student's t approximation procedure.
95% Adjusted Gamma UCL = Calculated using Adjusted Gamma distribution procedure.
95% Adjusted Gamma KM-UCL = Calculated using Kaplan-Meier Adjusted Gamma distribution procedure.
95% KM (t) UCL = Calculated using 95% Kaplan-Meier (Student's t approximation) non-parametric procedure.
95% KM (Chebyshev) UCL = Calculated using 95% Kaplan-Meier (Chebyshev inequality) non-parametric procedure.
99% KM (Chebyshev) UCL = Calculated using 99% Kaplan-Meier (Chebyshev inequality) non-parametric procedure.

(5) The UCL recommended by ProUCL is used (where mulitple values are recommended, the higher is used).
(a) When the maximum detected concentration is selected as the RME EPC, the arithmetic mean concentration is selected as the CTE EPC.
(b) Arithmetic mean concentration equals the maximum detected concentration, therefore, the maximum detected concentration is used as the CTE EPC.

Notes:

CAS = Chemical Abstracts Service.

CTE = Central Tendency Exposure.

EPC = Exposure point concentration.

RME = Reasonable Maximum Exposure.

PCBs = Polychlorinated biphenyls.

SVOCs = Semivolatile organic compounds.

UCL = Upper confidence limit.

ug/L = Micrograms per liter.

USEPA = United States Environmental Protection Agency.

(1) Arithmetic means were calculated using detected concentrations only.

(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.00. For data sets with multiple detection limits for non-detects, the use of the Kaplan-Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan-Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.
N = Normal; G = Gamma; NC = Not calculated.

(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.

(4) Indicates the statistic on which the exposure point concentration is based.
Maximum Concentration = Maximum detected concentration.
95% Adjusted Gamma UCL = Calculated using Adjusted Gamma distribution procedure.
95% KM (t) UCL = Calculated using 95% Kaplan-Meier (Student's t approximation) non-parametric procedure.

(5) The UCL recommended by ProUCL is used (where mulitple values are recommended, the higher is used).
(a) Maximum detected concentration used for EPC due to the low number of detections (less than 6) or small sample size (less than 10).
(b) The arithmetic mean concentration is essentially equal to the maximum detected concentration. Therefore, the maximum detected concentration is used as the CTE EPC.

Notes:
CAS = Chemical Abstracts Service.
CTE = Central Tendency Exposure.
COPC = Chemical of potential concern.
EPC = Exposure point concentration.
HHRA = Human Health Risk Assessment.
SVOCs = Semivolatile organic compounds.
UCL = Upper confidence limit.
ug/L = micrograms per liter.
ug/m3 = micrograms per cubic meter.
USEPA = United States Environmental Protection Agency.
VOCs = Volatile organic compounds.
(1) Arithmetic means were calculated using detected concentrations only.
(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.00. For data sets with multiple detection limits for non-detects, the use of the Kaplan-Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan-Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted.
N = Normal; LN = Lognormal; G = Gamma; ND = Not Discernable; NC = Not calculated.
(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only.
(4) Shower air EPCs were estimated based on the groundwater EPC using an attenuation factor calcluated using a trench air model,as discussed in the HHRA report text.

Notes:
CAS = Chemical Abstracts Service.
COPC = Chemical of potential concern.
EPC = Exposure point concentration.
HHRA = Human Health Risk Assessment.
RME = Reasonable Maximum Exposure.
SVOCs = Semivolatile organic compounds.
UCL = Upper confidence limit.
ug/L = micrograms per liter.
ug/m3 = micrograms per cubic meter.
USEPA = United States Environmental Protection Agency.
VOCs = Volatile organic compounds.
(1) Arithmetic means were calculated using detected concentrations only.
(2) UCL calculations were performed using USEPA's ProUCL software version 5.1.00. For data sets with multiple detection limits for non-detects, the use of the Kaplan-Meier non-parametric test procedure is recommended and used to calculate an appropriate UCL. For the Kaplan-Meier test procedure, the type of data distribution was determined using a series of tests (Shapiro-Wilk, Kolmogorov-Smirnov, Anderson-Darling) for normal, lognormal, or gamma data distributions. The results of these distribution tests determined which UCL calculation was performed. The UCL suggested by ProUCL is used, unless otherwise noted. In cases where more than one UCL is suggested, the higher UCL is used, unless otherwise noted
N = Normal; LN = Lognormal; G = Gamma; ND = Not Discernable; NC = Not calculated
(3) Equal to the maximum detected concentration.
J = The compound was positively identified; however, the associated numerical value is an estimated concentration only
(4) The indoor air EPC is estimated based on the groundwater EPC using the USEPA Johnson and Ettinger Model (JE Model) Spreadsheets as discussed in the HHRA report text
(5) The only difference between the residential and industrial indoor air modeling is the air exchange rate, which is 0.25/hour for residential and 1/hour for industrial
Therefore, the industrial indoor air EPCs were derived by dividing the residential indoor air EPCs by 4.

Exposure Route	Receptor Population	Receptor Age	Exposure Point	Parameter Code	Parameter Definition	Value	Units	Rationale/ Reference	Intake Equation/ Model Name
Inhalation	Construction Worker	Adult	Fire Training Area	CA	Chemical Concentration in Trench Air	Chemical Specific	ug/m^3	See Table 3s	Intake (ug/m^3) =
				ET	Exposure Time	4	hrs/day	(1)	$\frac{CA \times ET \times EF \times ED}{AT \times CF}$
				EF	Exposure Frequency	26	days/yr	MEDEP, 2013	
				ED	Exposure Duration	0.5	years	MEDEP, 2013	
				CF	Conversion Factor	24	hrs/day	--	
				ATc	Averaging Time - cancer	25,550	days	USEPA, 2014	
				ATnc	Averaging Time - noncancer	182.5	days	USEPA, 2014	

Notes:

RME - Reasonable Maximum Exposure.

1 - Construction worker is assumed to contact groundwater in an excavation trench for half of a typical 8-hour workday.

Sources:

USEPA, 2014: Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. February 6, 2014. Corrected September 2015.

MEDEP, 2013: Guidance for Human Health Risk Assessments for Hazardous Substances Sites in Maine. Standard Default Exposure Assumptions Table 1, Revised October 2013.

Unit Intake Calculations

Inhalation Intake [unitless] =(ET x EF x ED) / (AT x CF) [CA is factored into the risk calculation in Table 7s]

Cancer Inhalation Intake =	8.48E-05
Noncancer Inhalation Intake =	1.19E-02

Cancer risk from inhalation = Air concentration x Cancer Inhalation Intake x Inhalation Unit Risk

Hazard Index from inhalation = Air concentration x Noncancer Inhalation Intake / Inhalation Reference Concentration

Scenario Timeframe:	Current/Future
Medium:	Surface Water
Exposure Medium:	Surface Water

Exposure Route	Receptor Population	Receptor Age	Exposure Point	Parameter Code	Parameter Definition	Value	Units	Rationale/ Reference	Intake Equation/ Model Name

Notes:

RME - Reasonable Maximum Exposure.

1 - Professional judgment. Exposure frequency is equivalent to 5 days per week for 6 weeks based on the limited construction work expected to occur in the wetland area.

2 - Value is assumed to be one-tenth of that assumed to occur during a swimming event via incidental ingestion (based on MEDEP's (2013)) recommended ingestion rate during a swimming event).

Sources:

USEPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. EPA/540/R/99/005.

USEPA, 2014: Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. February 6, 2014. Corrected September 2015.

MEDEP, 2013: Guidance for Human Health Risk Assessments for Hazardous Substances Sites in Maine. Standard Default Exposure Assumptions Table 1, Revised October 2013.

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(L/ug)]= (IR x EF x ED x CF)/(BW x AT) [CW is factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(L/ug)(event/cm)]= (SA x EV x EF x ED x CF1 x CF2)/(BW x AT) [DA (including CW, PC, and ET) is factored into the risk calculation in Table 7s]

Cancer Ingestion Intake =	3.67E-11	Cancer Dermal Intake =	2.59E-08
Noncancer Ingestion Intake =	5.14E-09	Noncancer Dermal Intake =	3.62E-06

Cancer risk from ingestion = Surface water concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = Surface water concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = Surface water concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = Surface water concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

USEPA, 2016: USEPA Regional Screening Level (RSL) Calculator. May 2016 Version. Default values for Portland, Maine.

MEDEP, 2013: Guidance for Human Health Risk Assessments for Hazardous Substances Sites in Maine. Standard Default Exposure Assumptions Table 1, Revised October 2013.

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(kg/mg)] = (IR x EF x ED x CF x FI)/(BW x AT) [CS is factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(kg/mg)] = (SA x AF x EF x ED x CF)/(BW x AT) [CS and ABS are factored into the risk calculation in Table 7s]

Inhalation Intake [(ug/m^3)(kg/mg)] =(ET x EF x ED x CF2)/(PEF x AT x CF1) [CS is factored into the risk calculation in Table 7s]

Child:	Cancer Ingestion Intake =	2.82E-07	Cancer Dermal Intake =	6.69E-07	Cancer Inhalation Intake =	2.72E-09
	Noncancer Ingestion Intake =	3.29E-06	Noncancer Dermal Intake =	7.80E-06	Noncancer Inhalation Intake =	3.18E-08
Adult:	Cancer Ingestion Intake =	8.81E-08	Cancer Dermal Intake =	3.72E-07	Cancer Inhalation Intake =	9.07E-09
	Noncancer Ingestion Intake =	3.08E-07	Noncancer Dermal Intake =	1.30E-06	Noncancer Inhalation Intake =	3.18E-08

Cancer risk from ingestion = Soil concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = Soil concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = Soil concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = Soil concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

Cancer risk from inhalation = Air concentration x Cancer Inhalation Intake x Inhalation Unit Risk

Hazard Index from inhalation = Air concentration x Noncancer Inhalation Intake / Inhalation Reference Concentration

Scenario Timeframe:	Current/Future
Medium:	Surface Water
Exposure Medium:	Surface Water

Exposure Route	Receptor Population	Receptor Age	Exposure Point	Parameter Code	Parameter Definition	Value	Units	Rationale/ Reference	Intake Equation/ Model Name

Notes:

RME - Reasonable Maximum Exposure.

USEPA - United States Environmental Protection Agency.

1 - Professional judgment. Assumes one day a week for six months during the warm weather months.

2 - Children will be evaluated as one age group (0-6 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

3 - Adults will be evaluated as one age group (7-26 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

4 - Value is assumed to be one-tenth of that assumed to occur during a swimming event via incidental ingestion (based on MEDEP's (2013)) recommended ingestion rate during a swimming event).

Sources:

USEPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. EPA/540/R/99/005.

USEPA, 2014: Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. February 6, 2014. Corrected September 2015.

MEDEP, 2013: Guidance for Human Health Risk Assessments for Hazardous Substances Sites in Maine. Standard Default Exposure Assumptions Table 1, Revised October 2013.

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(L/ug)]= (IR x EF x ED x CF)/(BW x AT) [CW is factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(L/ug)(event/cm)]= (SA x EV x EF x ED x CF1 x CF2)/(BW x AT) [DA (including CW, PC, and ET) is factored into the risk calculation in Table 7s]

Child:	Cancer Ingestion Intake =	2.04E-09	Cancer Dermal Intake =	9.66E-07
	Noncancer Ingestion Intake =	2.37E-08	Noncancer Dermal Intake =	1.13E-05
Adult:	Cancer Ingestion Intake =	1.27E-09	Cancer Dermal Intake =	1.53E-06
	Noncancer Ingestion Intake =	4.45E-09	Noncancer Dermal Intake =	5.37E-06

Cancer risk from ingestion = Surface water concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = Surface water concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = Surface water concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = Surface water concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

VALUES USED FOR DAILY INTAKE CALCULATIONS

CENTRAL TENDENCY EXPOSURE - ON-SITE RECREATIONAL USER/TRESPASSER - SURFACE WATER

HUMAN HEALTH RISK ASSESSMENT

FIRE TRAINING AREA, NCTAMS LANT DET CUTLER

CUTLER, MAINE

Scenario Timeframe:	Current/Future
Medium:	Surface Water
Exposure Medium:	Surface Water

Exposure Route	Receptor Population	Receptor Age	Exposure Point	Parameter Code	Parameter Definition	Value	Units	Rationale/ Reference	Intake Equation/ Model Name

Notes:

RME - Reasonable Maximum Exposure.

USEPA - United States Environmental Protection Agency.

1 - Professional judgment. Assumes one day every other week in warm weather months.

2 - Children will be evaluated as one age group (0-6 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

3 - Adults will be evaluated as one age group (7-26 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

4 - Value is assumed to be one-tenth of that assumed to occur during a swimming event via incidental ingestion (based on MEDEP's (2013)) recommended ingestion rate during a swimming event).

Sources:

USEPA, 1989: Risk Assessment Guidance for Superfund. Vol 1: Human Health Evaluation Manual, Part A. EPA/540/1-86/060.

USEPA, 1993: Superfund's Standard Default Exposure Factors for the Central Tendency and Reasonable Maximum Exposure.

USEPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. EPA/540/R/99/005.

USEPA, 2014: Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. February 6, 2014. Corrected September 2015.

MEDEP, 2013: Guidance for Human Health Risk Assessments for Hazardous Substances Sites in Maine. Standard Default Exposure Assumptions Table 1, Revised October 2013.

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(L/ug)]= (IR x EF x ED x CF)/(BW x AT) [CW is factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(L/ug)(event/cm)]= (SA x EV x EF x ED x CF1 x CF2)/(BW x AT) [DA (including CW, PC, and ET) is factored into the risk calculation in Table 7s]

Child:	Cancer Ingestion Intake =	3.39E-10	Cancer Dermal Intake =	1.61E-07
	Noncancer Ingestion Intake =	1.19E-08	Noncancer Dermal Intake =	5.63E-06
Adult:	Cancer Ingestion Intake =	2.23E-10	Cancer Dermal Intake =	2.69E-07
	Noncancer Ingestion Intake =	2.23E-09	Noncancer Dermal Intake =	2.69E-06

Cancer risk from ingestion = Surface water concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = Surface water concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = Surface water concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = Surface water concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

USEPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. EPA/540/R/99/005.

USEPA, 2014: Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. February 6, 2014. Corrected September 2015.

USEPA, 2016: USEPA Regional Screening Level (RSL) Calculator. May 2016 Version. Default values for Portland, Maine.

MEDEP, 2013: Guidance for Human Health Risk Assessments for Hazardous Substances Sites in Maine. Standard Default Exposure Assumptions Table 1, Revised October 2013.

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(kg/mg)] = (IR x EF x ED x CF x FI)/(BW x AT) [CS is factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(kg/mg)] = (SA x AF x EF x ED x CF)/(BW x AT) [CS and ABS are factored into the risk calculation in Table 7s]

Inhalation Intake [$(ug/m^3)(kg/mg)$] =(ET x EF x ED x CF2)/(PEF x AT x CF1) [CS is factored into the risk calculation in Table 7s]

Cancer Ingestion Intake =	3.30E-08	Cancer Dermal Intake =	4.66E-08	Cancer Inhalation Intake =	2.72E-08
Noncancer Ingestion Intake =	2.57E-07	Noncancer Dermal Intake =	3.62E-07	Noncancer Inhalation Intake =	2.12E-07

Cancer risk from ingestion = Soil concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = Soil concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = Soil concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = Soil concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

Cancer risk from inhalation = Air concentration x Cancer Inhalation Intake x Inhalation Unit Risk

Hazard Index from inhalation = Air concentration x Noncancer Inhalation Intake / Inhalation Reference Concentration

Medium:	Soil
Exposure Medium:	Surface/Subsurface Soil

Exposure Route	Receptor Population	Receptor Age	Exposure Point	Parameter Code	Parameter Definition	Value	Units	Rationale/ Reference	Intake Equation/ Model Name

Notes:

USEPA - United States Environmental Protection Agency.

CTE - Central Tendency Exposure.

RME - Reasonable Maximum Exposure.

1 - Children will be evaluated as one age group (0-6 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

2 - Adults will be evaluated as one age group (7-26 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

3 - Professional judgment; conservatively assumes 100 percent of soil ingested is from the Site.

4 - Professional judgment. For some factors, CTE is assumed to be 50 percent of RME.

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(kg/mg)] = (IR x EF x ED x CF x FI)/(BW x AT) [CS is factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(kg/mg)] = (SA x AF x EF x ED x CF)/(BW x AT) [CS and ABS are factored into the risk calculation in Table 7s]

Inhalation Intake [(ug/m^3)(kg/mg)] =(ET x EF x ED x CF2)/(PEF x AT x CF1) [CS is factored into the risk calculation in Table 7s]

Child:	Cancer Ingestion Intake =	3.91E-08	Cancer Dermal Intake =	3.72E-08	Cancer Inhalation Intake =	9.07E-09	
	Noncancer Ingestion Intake =	1.37E-06	Noncancer Dermal Intake =	1.30E-06	Noncancer Inhalation Intake =	3.18E-07	
Adult:	Cancer Ingestion Intake =	1.28E-08	Cancer Dermal Intake =	1.55E-08	Cancer Inhalation Intake =	3.18E-08	
	Noncancer Ingestion Intake =	1.28E-07	Noncancer Dermal Intake =	1.55E-07	Noncancer Inhalation Intake =	3.18E-07	

Cancer risk from ingestion = Soil concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = Soil concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = Soil concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = Soil concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

Cancer risk from inhalation = Air concentration x Cancer Inhalation Intake x Inhalation Unit Risk

Hazard Index from inhalation = Air concentration x Noncancer Inhalation Intake / Inhalation Reference Concentration

Notes:

RME - Reasonable Maximum Exposure.

1 - Children will be evaluated as one age group (0-6 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

2 - Adults will be evaluated as one age group (7-26 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

Sources:

USEPA, 2014: Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. February 6, 2014. Corrected September 2015.

MEDEP, 2013: Guidance for Human Health Risk Assessments for Hazardous Substances Sites in Maine. Standard Default Exposure Assumptions Table 1, Revised October 2013.

Unit Intake Calculations

Inhalation Intake [unitless] =(ET x EF x ED) / (AT x CF) [CA is factored into the risk calculation in Table 7s]

Child:	Cancer Inhalation Intake =	8.22E-02
	Noncancer Inhalation Intake =	9.59E-01
Adult:	Cancer Inhalation Intake =	2.74E-01
	Noncancer Inhalation Intake =	9.59E-01

Cancer risk from inhalation = Air concentration x Cancer Inhalation Intake x Inhalation Unit Risk

Hazard Index from inhalation = Air concentration x Noncancer Inhalation Intake / Inhalation Reference Concentration

CUTLER, MAINE

Scenario Timeframe:	Future
Medium:	Surface Water
Exposure Medium:	Surface Water

Exposure Route	Receptor Population	Receptor Age	Exposure Point	Parameter Code	Parameter Definition	Value	Units	Rationale/ Reference	Intake Equation/ Model Name

Notes:

RME - Reasonable Maximum Exposure.

USEPA - United States Environmental Protection Agency.

1 - Professional judgment. Assumes one day a week for six months during the warm weather months.

2 - Children will be evaluated as one age group (0-6 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

3 - Adults will be evaluated as one age group (7-26 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

4 - Value is assumed to be one-tenth of that assumed to occur during a swimming event via incidental ingestion (based on MEDEP's (2013)) recommended ingestion rate during a swimming event).

Sources:

USEPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. EPA/540/R/99/005.

USEPA, 2014: Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. February 6, 2014. Corrected September 2015.

MEDEP, 2013: Guidance for Human Health Risk Assessments for Hazardous Substances Sites in Maine. Standard Default Exposure Assumptions Table 1, Revised October 2013.

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(L/ug)]= (IR x EF x ED x CF)/(BW x AT) [CW is factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(L/ug)(event/cm)]= (SA x EV x EF x ED x CF1 x CF2)/(BW x AT) [DA (including CW, PC, and ET) is factored into the risk calculation in Table 7s]

Child:	Cancer Ingestion Intake =	2.04E-09	Cancer Dermal Intake =	9.66E-07
	Noncancer Ingestion Intake =	2.37E-08	Noncancer Dermal Intake =	1.13E-05
Adult:	Cancer Ingestion Intake =	1.27E-09	Cancer Dermal Intake =	1.53E-06
	Noncancer Ingestion Intake =	4.45E-09	Noncancer Dermal Intake =	5.37E-06

Cancer risk from ingestion = Surface water concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = Surface water concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = Surface water concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = Surface water concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

VALUES USED FOR DAILY INTAKE CALCULATIONS

REASONABLE MAXIMUM EXPOSURE - HYPOTHETICAL FUTURE ON-SITE RESIDENT - SEDIMENT

HUMAN HEALTH RISK ASSESSMENT

FIRE TRAINING AREA, NCTAMS LANT DET CUTLER

CUTLER, MAINE

Scenario Timeframe:	Future
Medium:	Sediment
Exposure Medium:	Sediment

Exposure Route	Receptor Population	Receptor Age	Exposure Point	Parameter Code	Parameter Definition	Value	Units	Rationale/ Reference	Intake Equation/ Model Name

Notes:

USEPA - United States Environmental Protection Agency.

1 - Professional judgment. Assumes one day a week for six months during the warm weather months.

2 - Children will be evaluated as one age group (0-6 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

3 - Adults will be evaluated as one age group (7-26 years) for non-mutagenic chemicals in accordance with USEPA's Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005).

4 - Professional judgment; conservatively assumes 100 percent of sediment ingested is from the Site.

Sources:

USEPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. EPA/540/R/99/005.

USEPA, 2014: Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors. February 6, 2014. Corrected September 2015.

MEDEP, 2013: Guidance for Human Health Risk Assessments for Hazardous Substances Sites in Maine. Standard Default Exposure Assumptions Table 1, Revised October 2013.

Unit Intake Calculations

Incidental Ingestion Intake [(mg/kg-day)(kg/mg)] = (IR x EF x ED x CF x FI)/(BW x AT) [CS is factored into the risk calculation in Table 7s]

Dermal Intake [(mg/kg-day)(kg/mg)] = (SA x AF x EF x ED x CF)/(BW x AT) [CS and ABS are factored into the risk calculation in Table 7s]

Child:	Cancer Ingestion Intake =	8.14E-08	Cancer Dermal Intake =	1.93E-07
	Noncancer Ingestion Intake =	9.50E-07	Noncancer Dermal Intake =	2.25E-06
Adult:	Cancer Ingestion Intake =	2.54E-08	Cancer Dermal Intake =	1.07E-07
	Noncancer Ingestion Intake =	8.90E-08	Noncancer Dermal Intake =	3.76E-07

Cancer risk from ingestion = sediment concentration x Cancer Ingestion Intake x Oral Cancer Slope Factor

Cancer risk from dermal contact = sediment concentration x Cancer Dermal Intake x Absorption Factor x Dermal Cancer Slope Factor

Hazard Index from ingestion = sediment concentration x Noncancer Ingestion Intake / Oral Reference Dose

Hazard Index from dermal contact = sediment concentration x Noncancer Dermal Intake x Absorption Factor / Dermal Reference Dose

TABLE 5.1

NON-CANCER TOXICITY DATA -- ORAL/DERMAL

HUMAN HEALTH RISK ASSESSMENT

FIRE TRAINING AREA, NCTAMS LANT DET CUTLER

CUTLER, MAINE

Chemical of Potential Concern (1)	CAS Number	Chronic/ Subchronic (2)	Oral RfD		Oral Absorption Efficiency for Dermal (3)	Absorbed RfD for Dermal (4)		Primary Target Organ(s)	Combined Uncertainty/Modifying Factors	RfD:Target Organ(s)	
			Value	Units		Value	Units			Source(s)	Date(s) (MM/YYYY)

Notes:

ATSDR - Agency for Toxic Substances and Disease Registry

CAS - Chemical Abstracts Service.

IRIS - Integrated Risk Information System.

N/A - Not Applicable/Not Available.

MECDC - Maine Center for Disease Control and Prevention.

mg/kg-day - milligrams per kilogram per day.

PCBs - Polychlorinated biphenyls.

PFASs - Poly- and Perfluoroalkyl Substances.

PFOA - Perfluorooctanoic acid.

PFOS - Perfluorooctanesulfonic acid (Perfluorooctane sulfonate).

PPRTV - Provisional Peer Reviewed Toxicity Values.

RfD - Reference Dose.

SVOCs - Semi-volatile organic compounds.

USEPA - United States Environmental Protection Agency.

VOCs - Volatile organic compounds.

(1) The following surrogates were used for chemicals without toxicity values or multiple forms:

RfD for cadmium in water used for cadmium. Cadmium is not a COPC in soil or sediment.

RfD for hexavalent chromium used for chromium, total.

RfD for manganese, non-diet used.

When assessing exposure to manganese in soil or drinking water, IRIS recommends applying a modifying factor of 3 to the oral RfD of 0.14 mg/kg-day. The USEPA Regional Screening Level (RSL) User's Guide (2015) also indicates that the average dietary manganese content of the US diet (5 mg/day) be subtracted from the critical dose of 10 mg/day when assessing exposure to non-dietary manganese. Therefore, the RfD is (10 mg/day - 5 mg/day)/Modifying Factor (3) = 1.67 mg/day / 70 kg = 0.024 mg/kg-day.

RfD for thallium is based on thallium soluble salts. No PPRTVs were developed for thallium in the PPRTV document (USEPA, 2012) due to database deficiencies.

Appendix A of the PPRTV document indicates that it is inappropriate to derive provisional chronic or subchronic RfDs for thallium, but that information is available which, although insufficient to support derivation of a provisional toxicity value, under current guidelines, may be of limited use to risk assessors as a screening value. The use of this screening provisional value is highly uncertain but is the value used in the USEPA Regional Screening Level (RSL) Tables (USEPA, 2016).

RfD for vanadium is derived from the IRIS oral RfD for Vanadium Pentoxide.

The molecular weight (MW) of the oxide ion is factored out. Vanadium Pentoxide (V205) has a molecular weight of 181.88. The two atoms of Vanadium contribute 56% of the MW. Vanadium Pentoxide's oral RfD of 9E-03 mg/kg-day multiplied by 56% gives a Vanadium oral RfD of 5.04E-03 mg/kg-day.

RfD for endrin used for endrin keytone.

RfD for Aroclor 1254 used as a surrogate for Total PCBs.

(2) Published value where available. Where not available, when the chronic RfD is based on a subchronic study, a subchronic RfD has been developed by the elimination of the uncertainty factor for subchronic to chronic adjustment. If no subchronic data are available, the chronic RfD has been adopted as the subchronic RfD.

(3) Oral Absorption Efficiencies from Exhibit 4-1 (USEPA, 2004. Risk Assessment Guidance for Superfund, Part E).

(4) Calculated as: (oral RfD) x (oral to dermal adjustment factor).

(5) RfDs for PFOS and PFOA recommended by USEPA in the following documents published in May 2016: "Drinking Water Health Advisory for Perfluorooctane Sulfonate (PFOS)" and "Drinking Water Health Advisory for Perfluorooctanoic Acid (PFOA)". [EPA 822-R- RfD used in USEPA Regional Screening Level Calculator (accessed March 2017).

TABLE 5.2
NON-CANCER TOXICITY DATA -- INHALATION
HUMAN HEALTH RISK ASSESSMENT
FIRE TRAINING AREA, NCTAMS LANT DET CUTLER
CUTLER, MAINE

Chemical of Potential Concern (1)	CAS Number	Chronic/ Subchronic (2)	Inhalation RfC		Primary Target Organ(s)	Combined Uncertainty/Modifying Factors	RfC : Target Organ(s)	
			Value	Units			Source(s)	Date(s) (MM/YYYY)

Notes:

ATSDR - Agency for Toxic Substances and Disease Registry.

CalEPA - California Environmental Protection Agency. Office of Environmental Health Hazard Assessment (OEHHA) Toxicity Criteria Database. http://oehha.ca.gov/chemicals.

CAS - Chemical Abstracts Service.

IRIS - Integrated Risk Information System.

N/A - Not Applicable or Not Available.

PCBs - Polychlorinated biphenyls.

PFASs - Poly- and Perfluoroalkyl Substances.

PFOA - Perfluorooctanoic acid.

PFOS - Perfluorooctanesulfonic acid (Perfluorooctane sulfonate).

PPRTV - Provisional Peer Reviewed Toxicity Value.

RfC - Reference concentration.

RfD - Reference dose.

SVOCs - Semi-volatile organic compounds.

ug/m^3 - micrograms per cubic meter.

VOCs - Volatile organic compounds.

(1) The following surrogates were used for chemicals without toxicity values or multiple forms:
RfC for hexavalent chromium used for chromium, total.

(2) Published value where available. Where not available, when the chronic RfC is based on a subchronic study, a subchronic RfC has been developed by the elimination of the uncertainty factor for subchronic to chronic adjustment. If no subchronic data are available, the chronic RfD has been adopted as the subchronic RfD.

TABLE 6.1
CANCER TOXICITY DATA -- ORAL/DERMAL
HUMAN HEALTH RISK ASSESSMENT
FIRE TRAINING AREA, NCTAMS LANT DET CUTLER
CUTLER, MAINE

Chemical of Potential Concern (1)	CAS Number	Oral Cancer Slope Factor		Oral Absorption Efficiency for Dermal	Absorbed Cancer Slope Factor for Dermal (3)		Weight of Evidence/ Cancer Guideline Description	Oral CSF		Mutagen?
		Value	Units		Value	Units		Source(s)	Date(s) (MM/YYYY)	

Notes:

CAS - Chemical Abstracts Service.
CSF - Cancer slope factor.
IRIS - Integrated Risk Information System.
mg/kg-day - milligrams per kilogram per day.
N/A - Not Applicable/Not Available.

PCBs - Polychlorinated biphenyls.
PFASs - Poly- and Perfluoroalkyl Substances.
PFOA - Perfluorooctanoic acid.
PFOS - Perfluorooctanesulfonic acid (Perfluorooctane sulfonate).
SVOCs - Semi-volatile organic compounds.
USEPA - United States Environmental Protection Agency.
VOCs - Volatile organic compounds.

USEPA Group:

A - Human carcinogen
B1 - Probable human carcinogen - indicates that limited human data are available
B2 - Probable human carcinogen - indicates sufficient evidence in animals and inadequate or no evidence in humans
D - Not classifiable as a human carcinogen (by the oral route)

(1) The following surrogates were used for chemicals without toxicity values or multiple forms:
(2) Oral absorption efficiency exceeds 50%. Therefore, no adjustment of the oral slope factor is necessary (USEPA, 2004. Exhibit 4-1).
(3) Calculated as: (oral slope factor) / (oral to dermal adjustment factor)
(4) CSF for PFOA derived in the USEPA in "Health Effects Support Document for Perfluorooctanoic Acid (PFOA)" published by the USEPA Office of Water in May 2016 [EPA 822-R-16-003] and utilized in USEPA's Regional Screening Level Calculator (accessed March 2017).
(5) Value for continuous lifetime exposure from birth. Because the CSF accounts for mutagenic action, age dependent adjustments factors are not applied.
(6) Value for continuous lifetime exposure during adulthood. Age dependent adjustments factors are not applicable to adult receptors.
(7) For PCBs, the Reasonable Maximum Exposure (RME) slope factor presented represents the upper-bound slope factor for high risk and persistence situations. The Central Tendency Exposure (CTE) slope factor is 1 per mg/kg-day and represents the central-estimate slope factor.

Notes:

CAS - Chemical Abstracts Service.

CalEPA - California Environmental Protection Agency. Office of Environmental Health Hazard Assessment(OEHHA) Toxicity Criteria Database. http://oehha.ca.gov/chemicals.

CSF - Cancer slope factor.

IRIS - Integrated Risk Information System.

N/A - Not Applicable/Not Available.

PCBs - Polychlorinated biphenyls.

PFASs - Poly- and Perfluoroalkyl Substances.

PFOA - Perfluorooctanoic acid.

PFOS - Perfluorooctanesulfonic acid (Perfluorooctane sulfonate).

PPRTV - Provisional Peer Reviewed Toxicity Values.

SVOCs - Semi-volatile organic compounds.

ug/m^3 - micrograms per cubic meter.

USEPA - United States Environmental Protection Agency.

VOCs - Volatile organic compounds.

USEPA Group:

A - Human carcinogen

B1 - Probable human carcinogen - indicates that limited human data are available

B2 - Probable human carcinogen - indicates sufficient evidence in animals and inadequate or no evidence in humans

D - Not classifiable as a human carcinogen (by the oral route)

(1) The following surrogates were used for chemicals without toxicity values or multiple forms:
Unit risk factor for hexavalent chromium used for chromium, total.

(3) Value for continuous lifetime exposure from birth. Because the CSF accounts for mutagenic action, age dependent adjustment factors are not applied.

(4) Value for continuous lifetime exposure during adulthood. Age dependent adjustment factors are not applicable to adult receptors.

(5) Consistent with the IRIS file for PCBs, for inhalation of dust containing PCBs, the high risk and persistence slope factors are used. The Reasonable Maximum Exposure (RME) unit risk factor presented represents the upper-bound slope factor. The Central Tendency Exposure (CTE) unit risk factor is based on the central-estimate slope factor.
The unit risk factors were converted from the slope factors as follows:
Upper-bound unit risk facor: [2 $(mg/kg\text{-}day)^{-1}$ x (20 m^3/day/70 kg) x 1 mg/1000 ug] = 0.00057 $(ug/m^3)^{-1}$

Receptor Age: Adult and Child

Medium	Exposure Medium	Exposure Point	Chemical of Potential Concern	Carcinogenic Risk Young Child + Adult				Non-Carcinogenic Hazard Quotient Young Child				
				Ingestion	Inhalation	Dermal	Exposure Routes Total	Primary Target Organ	Ingestion	Inhalation	Dermal	Exposure Routes Total

Notes:

[BKG] Indicates risk driver found to have concentrations in site media less than or consistent with concentrations in background and therefore not considered to be site-related.

COPC - Chemical of potential concern.

HI - Hazard Index.

MECDC - Maine Center for Disease Control and Prevention.

N/A - Not applicable.

PCBs - Polychlorinated biphenyls.

RME - Reasonable Maximum Exposure.

SVOCs - Semivolatile organic compounds.

USEPA - United States Environmental Protection Agency.

VOCs - Volatile organic compounds.

(a) Totals calculated assuming potential receptors contact surface soil within the associated exposure point/area and sediment and surface water within the wetland.

(b) Totals calculated assuming potential receptors contact subsurface soil within the associated exposure point/area and sediment and surface water within the wetland.

TABLE 11.1
OVERALL SUMMARY OF POTENTIAL CANCER RISKS, NONCANCER HAZARDS AND RISK DRIVERS
CURRENT/FUTURE CONSTRUCTION WORKER
HUMAN HEALTH RISK ASSESSMENT
FIRE TRAINING AREA, NCTAMS LANT DET CUTLER
CUTLER, MAINE

Scenario Timeframe	Receptor	Exposure Scenario	Exposure Area	Media	Potential ELCR (a)	Potential HI All Target Endpoints (a)	Maximum Potential HI Per Target Endpoint (a)	Risk Drivers (b)

Acronyms:
CTE - Central Tencency Exposure.
ELCR - Excess lifetime cancer risk.
HI - Hazard Index.
MEDEP - Maine Department of Environmental Protection.
RME - Reasonable Maximum Exposure.
USEPA - United States Environmental Protection Agency.

Media:
GW - Groundwater.
SB - Subsurface Soil.
SD - Sediment.
SS - Surface Soil.
SW - Surface Water.

Chemicals:
PCBs - Polychlorinated Biphenyls.

Risk Driver Basis:
ca - based on cancer.
nc - based on noncancer.

Notes:
BKG - Indicates risk drivers found to have concentrations in site media less than or consistent with concentrations in background and therefore not considered to be site-related
Green shading indicates an exceedance of MEDEP's target risk level of $1x10^{-5}$.
Yellow shading indicates an exceedance ofUSEPA's target risk range of 10^{-6} to 10^{-4} and/or MEDEP/USEPA's target HI of 1 per target organ, at one significant figure

(a) This table presents a summary of the total potential risk and hazard by exposure area and media.
Potential risk and hazard calculations are presented in Risk Assessment Guidance for Superfund (RAGS) Part D Table 7.1.RME/CTE in Attachment E.
Summaries of total risk and hazard by chemical are presented in Risk Assessment Guidance for Superfund (RAGS) Part D Table 9.1.RME/CTE in Attachment F.
(b) Risk drivers are identified where the total ELCR or HI per target endpoint are greater than target levels. A risk driver is then defined per exposure scenario (i.e., RME/CTE/receptor/medium) as a chemical with an individual ELCR greater than $1x10^{-6}$ and/or hazard quotient greater than 1, based on one significant figure

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
FD - Field duplicate.
ft - feet.
J - Estimated value.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing only the detected individual compounds (i.e., Aroclor/xylene) concentrations. For samples without any detections of individual compounds (i.e., Aroclor/xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".
(c) Chromium III concentrations were calculated by the laboratory by subtracting chromium IV from total chromium, and were reported to two significant figures. Where chromium IV was not detected, the chromium III concentration was reported as the total chromium concentration at two significant figures.

Notes:
< - Result not detected above laboratory reporting limit.
CAS - Chemical Abstracts Service.
FD - Field duplicate.
ft - feet.
J - Estimated value.
mg/kg - milligram per kilogram.
N - Normal sample.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile organic compound.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
UR - Unreported/rejected.
VOC - Volatile organic compound.
(a) Lab calculated value; only used when individual compound data not available.
(b) Total concentrations for use in the risk assessment were calculated per sample by summing only the detected individual compounds (i.e., Aroclor/xylene) concentrati For samples without any detections of individual compounds (i.e., Aroclor/xylene), the maximum reporting detection limit within the sample is presented as a non-detect value. Calculated totals have a CAS number beginning with "RA-".
(c) Chromium III concentrations were calculated by the laboratory by subtracting chromium IV from total chromium, and were reported to two significant figures. Where chromium IV was not detected, the chromium III concentration was reported as the total chromium concentration at two significant figures.
